  - Utilizarea PyQGIS în aplicații personalizate
  - Rularea Aplicațiilor Personalizate
- **Technical notes on PyQt and SIP**

Python support was first introduced in QGIS 0.9. There are several ways to use Python in QGIS Desktop (covered in the following sections):

- Issue commands in the Python console within QGIS
- Create and use plugins
- Automatically run Python code when QGIS starts
- Create processing algorithms
- Create functions for expressions in QGIS
- Create custom applications based on the QGIS API

Python bindings are also available for QGIS Server, including Python plugins (see QGIS Server and Python) and Python bindings that can be used to embed QGIS Server into a Python application.

There is a complete QGIS API reference that documents the classes from the QGIS libraries. The Pythonic QGIS API (pyqgis) is nearly identical to the C++ API.
A good resource for learning how to perform common tasks is to download existing plugins from the plugin repository and examine their code.

### 1.1 Scripting in the Python Console

QGIS provides an integrated Python console for scripting. It can be opened from the Plugins ⚙️ Python Console menu:

![Python Console](image)

**Fig. 1.1: Consola Python din QGIS**

The screenshot above illustrates how to get the layer currently selected in the layer list, show its ID and optionally, if it is a vector layer, show the feature count. For interaction with the QGIS environment, there is an `iface` variable, which is an instance of `QgisInterface`. This interface allows access to the map canvas, menus, toolbars and other parts of the QGIS application.

For user convenience, the following statements are executed when the console is started (in the future it will be possible to set further initial commands)

```python
from qgis.core import *
import qgis.utils
```

For those which use the console often, it may be useful to set a shortcut for triggering the console (within Settings ⚙️ Keyboard shortcuts...)

### 1.2 Plugin-uri Python

The functionality of QGIS can be extended using plugins. Plugins can be written in Python. The main advantage over C++ plugins is simplicity of distribution (no compiling for each platform) and easier development.

Many plugins covering various functionality have been written since the introduction of Python support. The plugin installer allows users to easily fetch, upgrade and remove Python plugins. See the Python Plugins page for more information about plugins and plugin development.

Crearea de plugin-uri în Python este simplă, instrucțiuni detaliate găsindu-se în :ref:`developing_plugins`.

**Notă:** Python plugins are also available for QGIS server. See QGIS Server and Python for further details.
1.3 Running Python code when QGIS starts

Există două metode distincte de a rula cod Python de fiecare dată când porneşte QGIS.

1. Creating a startup.py script
2. Setting the PYQGIS_STARTUP environment variable to an existing Python file

1.3.1 Fişierul startup.py

Every time QGIS starts, the user’s Python home directory

- **Linux**: /.local/share/QGIS/QGIS3
- **Windows**: AppData\Roaming\QGIS\QGIS3
- **macOS**: Library/Application Support/QGIS/QGIS3

is searched for a file named startup.py. If that file exists, it is executed by the embedded Python interpreter.

**Nota:** The default path depends on the operating system. To find the path that will work for you, open the Python Console and run `QStandardPaths.standardLocations(QStandardPaths.AppDataLocation)` to see the list of default directories.

1.3.2 The PYQGIS_STARTUP environment variable

You can run Python code just before QGIS initialization completes by setting the PYQGIS_STARTUP environment variable to the path of an existing Python file.

This code will run before QGIS initialization is complete. This method is very useful for cleaning sys.path, which may have undesireable paths, or for isolating/loading the initial environment without requiring a virtual environment, e.g. homebrew or MacPorts installs on Mac.

1.4 Aplicaţii Python

It is often handy to create scripts for automating processes. With PyQGIS, this is perfectly possible — import the qgis.core module, initialize it and you are ready for the processing.

Or you may want to create an interactive application that uses GIS functionality — perform measurements, export a map as PDF, ... The qgis.gui module provides various GUI components, most notably the map canvas widget that can be incorporated into the application with support for zooming, panning and/or any further custom map tools.

PyQGIS custom applications or standalone scripts must be configured to locate the QGIS resources, such as projection information and providers for reading vector and raster layers. QGIS Resources are initialized by adding a few lines to the beginning of your application or script. The code to initialize QGIS for custom applications and standalone scripts is similar. Examples of each are provided below.

**Nota:** Do not use qgis.py as a name for your script. Python will not be able to import the bindings as the script’s name will shadow them.
1.4.1 Utilizarea PyQGIS în script-uri de sine stătătoare

To start a standalone script, initialize the QGIS resources at the beginning of the script:

```python
from qgis.core import *

# Supply path to qgis install location
QgsApplication.setPrefixPath("/path/to/qgis/installation", True)

# Create a reference to the QgsApplication. Setting the second argument to False disables the GUI.
qgs = QgsApplication([], False)

# Load providers
qgs.initQgis()

# Write your code here to load some layers, use processing algorithms, etc.

# Finally, exitQgis() is called to remove the provider and layer registries from memory
qgs.exitQgis()
```

First we import the qgis.core module and configure the prefix path. The prefix path is the location where QGIS is installed on your system. It is configured in the script by calling the `setPrefixPath` method. The second argument of `setPrefixPath` is set to `True`, specifying that default paths are to be used.

The QGIS install path varies by platform; the easiest way to find it for your system is to use the Scripting in the Python Console from within QGIS and look at the output from running `QgsApplication.prefixPath()`.

After the prefix path is configured, we save a reference to `QgsApplication` in the variable `qgs`. The second argument is set to `False`, specifying that we do not plan to use the GUI since we are writing a standalone script. With `QgsApplication` configured, we load the QGIS data providers and layer registry by calling the `qgs.initQgis()` method. With QGIS initialized, we are ready to write the rest of the script. Finally, we wrap up by calling `qgs.exitQgis()` to remove the data providers and layer registry from memory.

1.4.2 Utilizarea PyQGIS în aplicații personalizate

The only difference between Utilizarea PyQGIS în script-uri de sine stătătoare and a custom PyQGIS application is the second argument when instantiating the `QgsApplication`. Pass `True` instead of `False` to indicate that we plan to use a GUI.

```python
from qgis.core import *

# Supply the path to the qgis install location
QgsApplication.setPrefixPath("/path/to/qgis/installation", True)

# Create a reference to the QgsApplication.
# Setting the second argument to True enables the GUI. We need this since this is a custom application.
qgs = QgsApplication([], True)

# Load providers
qgs.initQgis()

# Write your code here to load some layers, use processing algorithms, etc.

# Finally, exitQgis() is called to remove the
```

(continues on next page)
Now you can work with the QGIS API - load layers and do some processing or fire up a GUI with a map canvas. The possibilities are endless :-)

1.4.3 Rularea Aplicațiilor Personalizate

You need to tell your system where to search for QGIS libraries and appropriate Python modules if they are not in a well-known location - otherwise Python will complain:

```
>>> import qgis.core
ImportError: No module named qgis.core
```

This can be fixed by setting the PYTHONPATH environment variable. In the following commands, `<qgispath>` should be replaced with your actual QGIS installation path:

- on Linux: `export PYTHONPATH=/<qgispath>/share/qgis/python`
- on Windows: `set PYTHONPATH=c:\<qgispath>\python`
- on macOS: `export PYTHONPATH=/<qgispath>/Contents/Resources/python`

Now, the path to the PyQGIS modules is known, but they depend on the qgis_core and qgis_gui libraries (the Python modules serve only as wrappers). The path to these libraries may be unknown to the operating system, and then you will get an import error again (the message might vary depending on the system):

```
>>> import qgis.core
ImportError: libqgis_core.so.3.2.0: cannot open shared object file: No such file or directory
```

Fix this by adding the directories where the QGIS libraries reside to the search path of the dynamic linker:

- on Linux: `export LD_LIBRARY_PATH=/<qgispath>/lib`
- on Windows: `set PATH=C:\<qgispath>\bin;C:\<qgispath>\apps\<qgisrelease>\bin;%PATH%` where `<qgisrelease>` should be replaced with the type of release you are targeting (eg, qgis-ltr, qgis, qgis-dev)

Aceste comenzi pot fi puse într-un script bootstrap, care se va ocupa de pornire. Atunci când livrați aplicații personalizate folosind PyQGIS, există, de obicei, două variante:

- require the user to install QGIS prior to installing your application. The application installer should look for default locations of QGIS libraries and allow the user to set the path if not found. This approach has the advantage of being simpler, however it requires the user to do more steps.
- să împachetati QGIS împreună cu aplicația dumneavoastră. Livrarea aplicației poate fi mai dificilă deoarece pachetul va fi foarte mare, dar utilizatorul va fi salvat de povara de a descărca și instala software suplimentar.

The two deployment models can be mixed. You can provide a standalone applications on Windows and macOS, but for Linux leave the installation of GIS up to the user and his package manager.
1.5 Technical notes on PyQt and SIP

We’ve decided for Python as it’s one of the most favoured languages for scripting. PyQGIS bindings in QGIS 3 depend on SIP and PyQt5. The reason for using SIP instead of the more widely used SWIG is that the QGIS code depends on Qt libraries. Python bindings for Qt (PyQt) are done using SIP and this allows seamless integration of PyQGIS with PyQt.

The code snippets on this page need the following imports if you’re outside the pyqgis console:

```python
from qgis.core import (QgsProject, QgsPathResolver)

from qgis.gui import (QgsLayerTreeMapCanvasBridge,
)```
Încărcarea proiectelor

Sometimes you need to load an existing project from a plugin or (more often) when developing a standalone QGIS Python application (see: Aplicații Python).

To load a project into the current QGIS application you need to create an instance of the QgsProject class. This is a singleton class, so you must use its instance() method to do it. You can call its read() method, passing the path of the project to be loaded:

```python
# If you are not inside a QGIS console you first need to import
# qgis and PyQt classes you will use in this script as shown below:
from qgis.core import QgsProject
# Get the project instance
project = QgsProject.instance()
# Print the current project file name (might be empty in case no projects have been loaded)
print(project.fileName())
# Load another project
import os
print(os.getcwd())
project.read('testdata/01_project.qgs')
print(project.fileName())
```

If you need to make modifications to the project (for example to add or remove some layers) and save your changes, call the write() method of your project instance. The write() method also accepts an optional path for saving the project to a new location:

```python
# Save the project to the same
project.write()
# ... or to a new file
project.write('testdata/my_new_qgis_project.qgs')
```

Both read() and write() functions return a boolean value that you can use to check if the operation was successful.

Notă: If you are writing a QGIS standalone application, in order to synchronise the loaded project with the canvas
you need to instantiate a `QgsLayerTreeMapCanvasBridge` as in the example below:

```python
bridge = QgsLayerTreeMapCanvasBridge( 
    QgsProject.instance().layerTreeRoot(), canvas)
# Now you can safely load your project and see it in the canvas
project.read('testdata/my_new_qgis_project.qgs')
...
```

## 2.1 Resolving bad paths

It can happen that layers loaded in the project are moved to another location. When the project is loaded again all the layer paths are broken.

The `QgsPathResolver` class with the `setPathPreprocessor()` allows setting a custom path pre-processor function, which allows for manipulation of paths and data sources prior to resolving them to file references or layer sources.

The processor function must accept a single string argument (representing the original file path or data source) and return a processed version of this path.

The path pre-processor function is called **before** any bad layer handler.

Some use cases:

1. replace an outdated path:

   ```python
def my_processor(path):
        return path.replace('c:/Users/ClintBarton/Documents/Projects', 'x:/→Projects/')
QgsPathResolver.setPathPreprocessor(my_processor)
```

2. replace a database host address with a new one:

   ```python
def my_processor(path):
        return path.replace('host=10.1.1.115', 'host=10.1.1.116')
QgsPathResolver.setPathPreprocessor(my_processor)
```

3. replace stored database credentials with new ones:

   ```python
def my_processor(path):
        path= path.replace("user='gis_team'", "user='team_awesome'")
        path = path.replace("password='cats'", "password='g7as!m'*")
        return path
QgsPathResolver.setPathPreprocessor(my_processor)
```
Încărcarea Straturilor

The code snippets on this page need the following imports:

```python
import os  # This is needed in the pyqgis console also
from qgis.core import (QgsVectorLayer)
```

- *Straturile Vectoriale*
- *Straturile Raster*
- *QgsProject instance*

Hai de să deschidem mai multe straturi cu date. QGIS recunoaște straturile vectoriale și pe cele de tip raster. În plus, sunt disponibile și tipurile de straturi personalizate, dar pe acestea nu le vom discuta aici.

### 3.1 Straturile Vectoriale

To create and add a vector layer instance to the project, specify the layer’s data source identifier, name for the layer and provider’s name:

```python
# get the path to the shapefile e.g. /home/project/data/ports.shp
path_to_airports_layer = "testdata/airports.shp"

# The format is:
# vlayer = QgsVectorLayer(data_source, layer_name, provider_name)

vlayer = QgsVectorLayer(path_to_airports_layer, "Airports layer", "ogr")

if not vlayer.isValid():
    print("Layer failed to load!")
else:
    QgsProject.instance().addMapLayer(vlayer)
```

Identificatorul sursei de date reprezintă un sir specific pentru fiecare furnizor de date vectoriale în parte. Numele stratului se va afișa în lista straturilor. Este important să se verifice dacă stratul a fost încărcat cu succes. În cazul
neîncărcării cu succes, va fi returnată o instanță de strat nevalid.

For a geopackage vector layer:

1. # get the path to a geopackage  e.g. /usr/share/qgis/resources/data/world_map.gpkg
2. path_to_gpkg = os.path.join(QgsApplication.pkgDataPath(), "resources", "data", "world_map.gpkg")
3. # append the layername part
gpkg_countries_layer = path_to_gpkg + "|layername=countries"
4. # e.g. gpkg_places_layer = "/usr/share/qgis/resources/data/world_map.gpkg/layername=countries"
vlayer = QgsVectorLayer(gpkg_countries_layer, "Countries layer", "ogr")
5. if not vlayer.isValid():
   print("Layer failed to load!")
6. else:
   QgsProject.instance().addMapLayer(vlayer)

The quickest way to open and display a vector layer in QGIS is the addVectorLayer() method of the QgsInterface:

vlayer = iface.addVectorLayer(path_to_airports_layer, "Airports layer", "ogr")

if not vlayer:
   print("Layer failed to load!")

This creates a new layer and adds it to the current QGIS project (making it appear in the layer list) in one step. The function returns the layer instance or None if the layer couldn’t be loaded.

Lista de mai jos arată modul de accesare a diverselor surse de date, cu ajutorul furnizorilor de date vectoriale:

- OGR library (Shapefile and many other file formats) — data source is the path to the file:
  - for Shapefile:
    vlayer = QgsVectorLayer("testdata/airports.shp", "layer_name_you_like", "ogr")
    QgsProject.instance().addMapLayer(vlayer)
  - for dxf (note the internal options in data source uri):
    uri = "testdata/sample.dxf|layername=entities|geometrytype=Polygon"
    vlayer = QgsVectorLayer(uri, "layer_name_you_like", "ogr")
    QgsProject.instance().addMapLayer(vlayer)

- PostGIS database - data source is a string with all information needed to create a connection to PostgreSQL database.

  QgsDataSourceUri class can generate this string for you. Note that QGIS has to be compiled with Postgres support, otherwise this provider isn’t available:

  uri = QgsDataSourceUri()
  # set host name, port, database name, username and password
  uri.setConnection("localhost", "5432", "dbname", "johny", "xxx")
  # set database schema, table name, geometry column and optionally
  # subset (WHERE clause)
  uri.setDataSource("public", "roads", "the_geom", cityid = 2643, "primary_key__field")
  vlayer = QgsVectorLayer(uri.uri(False), "layer name you like", "postgres")

Notă: The False argument passed to uri.uri(False) prevents the expansion of the authentication configuration parameters, if you are not using any authentication configuration this argument does not make any difference.
• CSV or other delimited text files — to open a file with a semicolon as a delimiter, with field „x” for X coordinate and field „y” for Y coordinate you would use something like this:

```python
uri = "file:///testdata/delimited_xy.csv?delimiter=/&xField=/&yField=/".
--format(os.getcwd(), ";", "x", "y")
vlayer = QgsVectorLayer(uri, "layer name you like", "delimitedtext")
QgsProject.instance().addMapLayer(vlayer)
```

**Nota:** The provider string is structured as a URL, so the path must be prefixed with `file://`. Also it allows WKT (well known text) formatted geometries as an alternative to `x` and `y` fields, and allows the coordinate reference system to be specified. For example:

```python
uri = "file:///some/path/file.csv?delimiter=|
--format(""," shape")
```

• Fisier GPX — furnizorul de date „gpx” citește urme, rute și puncte de referință din fisier gpx. Pentru a deschide un fisier, tipul (urmă/traseu/punct de referință) trebuie să fie specificat ca parte a url-ului:

```python
uri = "testdata/layers.gpx?type=track"
vlayer = QgsVectorLayer(uri, "layer name you like", "gpx")
QgsProject.instance().addMapLayer(vlayer)
```

• SpatiaLite database — Similarly to PostGIS databases, `QgsDataSourceUri` can be used for generation of data source identifier:

```python
uri = QgsDataSourceUri()
uri.setDatabase('/home/martin/test-2.3.sqlite')
schema = '
    table = 'Towns'
geom_column = 'Geometry'
uri.setDataSource(schema, table, geom_column)
display_name = 'Towns'
vlayer = QgsVectorLayer(uri.uri(), display_name, 'spatialite')
QgsProject.instance().addMapLayer(vlayer)
```

• Geometrii MySQL bazate pe WKB, prin OGR — sursa de date o reprezintă sîntul de conectare la tabelă:

```python
uri = "MySQL:dbname,host=localhost,port=3306,user=root,
--password=xxx|layername=my_table"
vlayer = QgsVectorLayer( uri, "my table", "ogr" )
QgsProject.instance().addMapLayer(vlayer)
```

• WFS connection: the connection is defined with a URI and using the WFS provider:

```python
uri = "https://demo.geo-solutions.it/geoserver/ows?service=WFS&version=1.1.0&
--request=GetFeature&typename=geosolutions:regioni"
vlayer = QgsVectorLayer(uri, "my wfs layer", "WFS")
QgsProject.instance().addMapLayer(vlayer)
```

Identificatorul URI poate fi creat folosindu-se biblioteca standard `urllib`:

```python
import urllib

params = {
    'service': 'WFS',
    'version': '1.1.0',
    'request': 'GetFeature',
    'typename': 'geosolutions:regioni',
    'srsname': 'EPSG:4326'
}
```

(continues on next page)
uri2 = 'https://demo.geo-solutions.it/geoserver/ows?' + urllib.parse.unquote(urllib.parse.urlencode(params))

Notă: You can change the data source of an existing layer by calling `setDataSource()` on a `QgsVectorLayer` instance, as in the following example:

```python
uri = "https://demo.geo-solutions.it/geoserver/ows?service=WFS&version=1.1.0&request=GetFeature&typename=geosolutions:regioni"
provider_options = QgsDataProvider.ProviderOptions()
# Use project's transform context
provider_options.transformContext = QgsProject.instance().transformContext()
vlayer.setDataSource(uri, "layer name you like", "WFS", provider_options)
QgsProject.instance().addMapLayer(vlayer)
```

### 3.2 Straturile Raster

For accessing raster files, GDAL library is used. It supports a wide range of file formats. In case you have troubles with opening some files, check whether your GDAL has support for the particular format (not all formats are available by default). To load a raster from a file, specify its filename and display name:

```python
# get the path to a tif file e.g. /home/project/data/srtm.tif
path_to_tif = "qgis-projects/python_cookbook/data/srtm.tif"
rlayer = QgsRasterLayer(path_to_tif, "SRTM layer name")
if not rlayer.isValid():
    print("Layer failed to load!")
```

To load a raster from a geopackage:

```python
# get the path to a geopackage e.g. /home/project/data/data.gpkg
path_to_gpkg = os.path.join(os.getcwd(), "testdata", "sublayers.gpkg")
# gpkg_raster_layer = "GPKG:/home/project/data/data.gpkg:srtm"
gpkg_raster_layer = "GPKG:" + path_to_gpkg + ":srtm"
rlayer = QgsRasterLayer(gpkg_raster_layer, "layer name you like", "gdal")
if not rlayer.isValid():
    print("Layer failed to load!")
```

Similarly to vector layers, raster layers can be loaded using the `addRasterLayer` function of the `QgisInterface` object:

```python
iface.addRasterLayer(path_to_tif, "layer name you like")
```

This creates a new layer and adds it to the current project (making it appear in the layer list) in one step.

To load a PostGIS raster:

PostGIS rasters, similar to PostGIS vectors, can be added to a project using a URI string. It is efficient to create a dictionary of strings for the database connection parameters. The dictionary is then loaded into an empty URI, before adding the raster. Note that None should be used when it is desired to leave the parameter blank:

```python
uri_config = {
    # a dictionary of database parameters
    'dbname': 'gis_db', # The PostgreSQL database to connect to.
    'host': 'localhost', # The host IP address or localhost.
}
```
'port': '5432', # The port to connect on.
'sslmode': 'disable', # The SSL/TLS mode. Options: allow, disable, prefer,_
            require, verify-ca, verify-full
# user and password are not needed if stored in the authcfg or service
'user': None, # The PostgreSQL user name, also accepts the new WFS_
            provider naming.
'password': None, # The PostgreSQL password for the user.
'service': None, # The PostgreSQL service to be used for connection to the_-
            database.
'authcfg': 'QconfigId', # The QGIS athentication database ID holding connection_-
            details.
# table and raster column details
'schema': 'public', # The database schema that the table is located in.
'table': 'my_rasters', # The database table to be loaded.
'column': 'rast', # raster column in PostGIS table
'mode': '2', # GDAL 'mode' parameter, 2 union raster tiles, 1 separate_-
            tiles (may require user input)
'sql': None, # An SQL WHERE clause.
'key': None, # A key column from the table.
'srid': None, # A string designating the SRID of the coordinate_-
            reference system.
'estimatedmetadata': 'False', # A boolean value telling if the metadata is_-
            estimated.
'type': None, # A WKT string designating the WKB Type.
'selectatid': None, # Set to True to disable selection by feature ID.
'options': None, # other PostgreSQL connection options not in this list.
'connect_timeout': None,
'hostaddr': None,
'driver': None,
'tty': None,
'requiressl': None,
'krbsrvname': None,
'gsslib': None,
}
# configure the URI string with the dictionary
uri = QgsDataSourceUri()
for param in uri_config:
    if (uri_config[param] != None):
        uri.setParam(param, uri_config[param]) # add parameters to the URI
# the raster can now be loaded into the project using the URI string and GDAL data_-
            provider
rlayer = iface.addRasterLayer('PG:' + uri.uri(False), "raster layer name", "gdal")

Straturile raster pot fi, de asemenea, create dintr-un serviciu WCS:

```python
layer_name = 'nurc:mosaic'
uri = "https://demo.geo-solutions.it/geoserver/ows?identifier={}".format(layer_-
            name)
rlayer = QgsRasterLayer(uri, 'my wcs layer', 'wcs')
```

Here is a description of the parameters that the WCS URI can contain:

WCS URI is composed of key=value pairs separated by &. It is the same format like query string in URL, encoded the same way. QgsDataSourceUri should be used to construct the URI to ensure that special characters are encoded properly.

- **url** (required) : WCS Server URL. Do not use VERSION in URL, because each version of WCS is using different parameter name for GetCapabilities version, see param version.
  
  - **identifier** (required) : Coverage name
  
  - **time** (optional) : time position or time period (beginPosition/endPosition[/timeResolution])

3.2. Straturile Raster
• **format** (optional): Supported format name. Default is the first supported format with tif in name or the first supported format.

• **crs** (optional): CRS in form AUTHORITY:ID, e.g. EPSG:4326. Default is EPSG:4326 if supported or the first supported CRS.

• **username** (optional): Username for basic authentication.

• **password** (optional): Password for basic authentication.

• **IgnoreGetMapUrl** (optional, hack): If specified (set to 1), ignore GetCoverage URL advertised by GetCapabilities. May be necessary if a server is not configured properly.

• **InvertAxisOrientation** (optional, hack): If specified (set to 1), switch axis in GetCoverage request. May be necessary for geographic CRS if a server is using wrong axis order.

• **IgnoreAxisOrientation** (optional, hack): If specified (set to 1), do not invert axis orientation according to WCS standard for geographic CRS.

• **cache** (optional): cache load control, as described in QNetworkRequest::CacheLoadControl, but request is resend as PreferCache if failed with AlwaysCache. Allowed values: AlwaysCache, PreferCache, PreferNetwork, AlwaysNetwork. Default is AlwaysCache.

Alternativ, puteți încărca un strat raster de pe un server WMS. Cu toate acestea, în prezent, nu este posibilă accesarea din API a răspunsului GetCapabilities — trebuie să cunoașteți straturile dorite:

```python
urlWithParams = "crs=EPSG:4326&format=image/png&layers=tasmania&styles&url=https://demo.geo-solutions.it/geoserver/ows"
rlayer = QgsRasterLayer(urlWithParams, 'some layer name', 'wms')
if not rlayer.isValid():
    print("Layer failed to load!")
```

### 3.3 QgsProject instance

If you would like to use the opened layers for rendering, do not forget to add them to the QgsProject instance. The QgsProject instance takes ownership of layers and they can be later accessed from any part of the application by their unique ID. When the layer is removed from the project, it gets deleted, too. Layers can be removed by the user in the QGIS interface, or via Python using the removeMapLayer() method.

Adding a layer to the current project is done using the addMapLayer() method:

```python
QgsProject.instance().addMapLayer(rlayer)
```

To add a layer at an absolute position:

```python
# first add the layer without showing it
QgsProject.instance().addMapLayer(rlayer, False)
# obtain the layer tree of the top-level group in the project
layerTree = iface.layerTreeCanvasBridge().rootGroup()
# the position is a number starting from 0, with -1 an alias for the end
layerTree.insertChildNode(-1, QgsLayerTreeLayer(rlayer))
```

If you want to delete the layer use the removeMapLayer() method:

```python
# QgsProject.instance().removeMapLayer(layer_id)
QgsProject.instance().removeMapLayer(rlayer.id())
```

In the above code, the layer id is passed (you can get it calling the id() method of the layer), but you can also pass the layer object itself.

For a list of loaded layers and layer ids, use the mapLayers() method:
QgsProject.instance().mapLayers()

The code snippets on this page need the following imports if you're outside the pyqgis console:

```python
from qgis.core import (QgsProject, QgsVectorLayer,
)```

3.3. QgsProject instance
Capitolul 3. Încărcarea Straturilor
Accessing the Table Of Contents (TOC)

- **The QgsProject class**
- **QgsLayerTreeGroup class**

You can use different classes to access all the loaded layers in the TOC and use them to retrieve information:

- QgsProject
- QgsLayerTreeGroup

### 4.1 The QgsProject class

You can use `QgsProject` to retrieve information about the TOC and all the layers loaded.

You have to create an instance of `QgsProject` and use its methods to get the loaded layers.

The main method is `mapLayers()`. It will return a dictionary of the loaded layers:

```python
layers = QgsProject.instance().mapLayers()
print(layers)
```

```
{'countries_89ae1b0f_f41b_4f42_bca4_caf55ddbe4b6': <QgsMapLayer: 'countries' (ogr)>}
```

The dictionary keys are the unique layer ids while the values are the related objects.

It is now straightforward to obtain any other information about the layers:

```python
# list of layer names using list comprehension
l = [layer.name() for layer in QgsProject.instance().mapLayers().values()]
# dictionary with key = layer name and value = layer object
layers_list = {}
for l in QgsProject.instance().mapLayers().values():
    layers_list[l.name()] = l
print(layers_list)
```
You can also query the TOC using the name of the layer:

country_layer = QgsProject.instance().mapLayersByName("countries")[0]

**Nota:** A list with all the matching layers is returned, so we index with [0] to get the first layer with this name.

### 4.2 QgsLayerTreeGroup class

The layer tree is a classical tree structure built of nodes. There are currently two types of nodes: group nodes (QgsLayerTreeGroup) and layer nodes (QgsLayerTreeLayer).

**Nota:** for more information you can read these blog posts of Martin Dobias: Part 1 Part 2 Part 3

The project layer tree can be accessed easily with the method *layerTreeRoot()* of the *QgsProject* class:

```python
root = QgsProject.instance().layerTreeRoot()
```

*root* is a group node and has children:

```python
root.children()
```

A list of direct children is returned. Sub group children should be accessed from their own direct parent.

We can retrieve one of the children:

```python
child0 = root.children()[0]
print(child0)
```

```python
<qgis._core.QgsLayerTreeLayer object at 0x7f1e1ea54168>
```

Layers can also be retrieved using their (unique) id:

```python
ids = root.findLayerIds()
# access the first layer of the ids list
root.findLayer(ids[0])
```

And groups can also be searched using their names:

```python
root.findGroup('Group Name')
```

QgsLayerTreeGroup has many other useful methods that can be used to obtain more information about the TOC:

```python
# list of all the checked layers in the TOC
checked_layers = root.checkedLayers()
print(checked_layers)
```

```python
[<QgsMapLayer: 'countries' (ogr)>]
```

Now let’s add some layers to the project’s layer tree. There are two ways of doing that:

1. **Explicit addition** using the *addLayer()* or *insertLayer()* functions:
1. # create a temporary layer
2. layer1 = QgsVectorLayer("path_to_layer", "Layer 1", "memory")
3. # add the layer to the legend, last position
4. root.addLayer(layer1)
5. # add the layer at given position
6. root.insertLayer(5, layer1)

2. Implicit addition: since the project’s layer tree is connected to the layer registry it is enough to add a layer to the map layer registry:

QgsProject.instance().addMapLayer(layer1)

You can switch between QgsVectorLayer and QgsLayerTreeLayer easily:

node_layer = root.findLayer(country_layer.id())
print("Layer node:", node_layer)
print("Map layer:", node_layer.layer())

Layer node: <qgis._core.QgsLayerTreeLayer object at 0x7fecceb46ca8>
Map layer: <QgsMapLayer: 'countries' (ogr)>

Groups can be added with the addGroup() method. In the example below, the former will add a group to the end of the TOC while for the latter you can add another group within an existing one:

node_group1 = root.addGroup('Simple Group')
# add a sub-group to Simple Group
node_subgroup1 = node_group1.addGroup("I'm a sub group")

To moving nodes and groups there are many useful methods.

Moving an existing node is done in three steps:

1. cloning the existing node
2. moving the cloned node to the desired position
3. deleting the original node

# clone the group
cloned_group1 = node_group1.clone()
# move the node (along with sub-groups and layers) to the top
root.insertChildNode(0, cloned_group1)
# remove the original node
root.removeChildNode(node_group1)

It is a little bit more complicated to move a layer around in the legend:

# get a QgsVectorLayer
vl = QgsProject.instance().mapLayersByName("countries")[0]
# create a QgsLayerTreeLayer object from vl by its id
myvl = root.findLayer(vl.id())
# clone the myvl QgsLayerTreeLayer object
myvclone = myvl.clone()
# get the parent. If None (layer is not in group) returns ''
parent = myvl.parent()
# move the cloned layer to the top (0)
parent.insertChildNode(0, myvclone)
# remove the original myvl
root.removeChildNode(myvl)

or moving it to an existing group:
```python
# get a QgsVectorLayer
vl = QgsProject.instance().mapLayersByName("countries")[0]

# create a QgsLayerTreeLayer object from vl by its id
myvl = root.findLayer(vl.id())

# clone the myvl QgsLayerTreeLayer object
myvlc = myvl.clone()

# create a new group
group1 = root.addGroup("Group1")

# get the parent. If None (layer is not in group) returns ''
parent = myvl.parent()

# move the cloned layer to the top (0)
group1.insertChildNode(0, myvlc)

# remove the QgsLayerTreeLayer from its parent
parent.removeChildNode(myvl)

Some other methods that can be used to modify the groups and layers:

node_group1 = root.findGroup("Group1")

# change the name of the group
node_group1.setName("Group X")

node_layer2 = root.findLayer(country_layer.id())

# change the name of the layer
node_layer2.setName("Layer X")

# change the visibility of a layer
node_group1.setItemVisibilityChecked(True)
node_layer2.setItemVisibilityChecked(False)

# expand/collapse the group view
node_group1.setExpanded(True)
node_group1.setExpanded(False)

The code snippets on this page need the following imports if you’re outside the pyqgis console:

```
Utilizarea straturilor raster

5.1 Detaliile stratului

A raster layer consists of one or more raster bands — referred to as single band and multi band rasters. One band represents a matrix of values. A color image (e.g. aerial photo) is a raster consisting of red, blue and green bands. Single band rasters typically represent either continuous variables (e.g. elevation) or discrete variables (e.g. land use). In some cases, a raster layer comes with a palette and the raster values refer to the colors stored in the palette.

The following code assumes `rlayer` is a `QgsRasterLayer` object.

```python
rlayer = QgsProject.instance().mapLayersByName('srtm')[0]
# get the resolution of the raster in layer unit
print(rlayer.width(), rlayer.height())
919 619

# get the extent of the layer as QgsRectangle
print(rlayer.extent())
"""QgsRectangle: 20.06856808199999875 -34.2700107699999896, 20.83945284300000012 -33.75077500700000144"

# get the extent of the layer as Strings
print(rlayer.extent().toString())
"20.0685680819999988,-34.27001076999999 -20.8394528430000001,-33.75077500700000014"

# get the raster type: 0 = GrayOrUndefined (single band), 1 = Palette (single band), 2 = Multiband
print(rlayer.rasterType())
0

# get the total band count of the raster
print(rlayer.bandCount())
21"""
# get all the available metadata as a QgsLayerMetadata object
print(rlayer.metadata())

<qgis._core.QgsLayerMetadata object at 0x13711d558>

## 5.2 Render

When a raster layer is loaded, it gets a default renderer based on its type. It can be altered either in the layer properties or programmatically.

Pentru a interoga renderul curent:

print(rlayer.renderer())

<qgis._core.QgsSingleBandGrayRenderer object at 0x7f471c1da8a0>

print(rlayer.renderer().type())

singlebandgray

To set a renderer, use the `setRenderer` method of `QgsRasterLayer`. There are a number of renderer classes (derived from `QgsRasterRenderer`):

- `QgsMultiBandColorRenderer`
- `QgsPalettedRasterRenderer`
- `QgsSingleBandColorDataRenderer`
- `QgsSingleBandGrayRenderer`
- `QgsSingleBandPseudoColorRenderer`

Single band raster layers can be drawn either in gray colors (low values = black, high values = white) or with a pseudocolor algorithm that assigns colors to the values. Single band rasters with a palette can also be drawn using the palette. Multiband layers are typically drawn by mapping the bands to RGB colors. Another possibility is to use just one band for drawing.

### 5.2.1 Rastere cu o singură bandă

Let’s say we want a render single band raster layer with colors ranging from green to yellow (corresponding to pixel values from 0 to 255). In the first stage we will prepare a `QgsRasterShader` object and configure its shader function:

```python
fcn = QgsColorRampShader()
fcn.setColorRampType(QgsColorRampShader.Interpolated)
lst = [QgsColorRampShader.ColorRampItem(0, QColor(0,255,0)),
      QgsColorRampShader.ColorRampItem(255, QColor(255,255,0))]
fcn.setColorRampItemList(lst)
shader = QgsRasterShader()
shader.setRasterShaderFunction(fcn)
```

The shader maps the colors as specified by its color map. The color map is provided as a list of pixel values with associated colors. There are three modes of interpolation:

- **linear (Interpolated):** the color is linearly interpolated from the color map entries above and below the pixel value
• discrete (Discrete): the color is taken from the closest color map entry with equal or higher value
• exact (Exact): the color is not interpolated, only pixels with values equal to color map entries will be drawn

In the second step we will associate this shader with the raster layer:

```python
renderer = QgsSingleBandPseudoColorRenderer(rlayer.dataProvider(), 1, shader)
rlayer.setRenderer(renderer)
```

The number 1 in the code above is the band number (raster bands are indexed from one).

Finally we have to use the `triggerRepaint` method to see the results:

```python
rlayer.triggerRepaint()
```

### 5.2.2 Rastere multibandă

By default, QGIS maps the first three bands to red, green and blue to create a color image (this is the `MultiBand-Color` drawing style. In some cases you might want to override these setting. The following code interchanges red band (1) and green band (2):

```python
rlayer_multi = QgsProject.instance().mapLayersByName('multiband')[0]
rlayer_multi.renderer().setGreenBand(1)
rlayer_multi.renderer().setRedBand(2)
```

In case only one band is necessary for visualization of the raster, single band drawing can be chosen, either gray levels or pseudocolor.

We have to use `triggerRepaint` to update the map and see the result:

```python
rlayer_multi.triggerRepaint()
```

### 5.3 Interogarea valorilor

Raster values can be queried using the `sample` method of the `QgsRasterDataProvider` class. You have to specify a `QgsPointXY` and the band number of the raster layer you want to query. The method returns a tuple with the value and `True` or `False` depending on the results:

```python
val, res = rlayer.dataProvider().sample(QgsPointXY(20.50, -34), 1)
```

Another method to query raster values is using the `identify` method that returns a `QgsRasterIdentifyResult` object.

```python
ident = rlayer.dataProvider().identify(QgsPointXY(20.5, -34), QgsRaster.IdentifyFormatValue)
if ident.isValid():
    print(ident.results())
```

```python
{(1: 323.0)}
```

In this case, the `results` method returns a dictionary, with band indices as keys, and band values as values. For instance, something like `{1: 323.0}`

The code snippets on this page need the following imports if you’re outside the pyqgis console:
from qgis.core import (QgsApplication,
QgsDataSourceUri,
QgsCategorizedSymbolRenderer,
QgsClassificationRange,
QgsPointXY,
QgsProject,
QgsExpression,
QgsField,
QgsFields,
QgsFeature,
QgsFeatureRequest,
QgsFeatureRenderer,
QgsGeometry,
QgsGraduatedSymbolRenderer,
QgsMarkerSymbol,
QgsMessageLog,
QgsRectangle,
QgsRendererCategory,
QgsRendererRange,
QgsSymbol,
QgsVectorDataProvider,
QgsVectorLayer,
QgsVectorFileWriter,
QgsWkbTypes,
QgsSpatialIndex,
)

from qgis.core.additions.edit import edit

from qgis.QtGui import (QColor,
)
Utilizarea straturilor vectoriale

• **Obtinerea informațiilor despre atribute**

• **Iterații în straturile vectoriale**

• **Selectarea entităților**
  – Accesarea atributelor
  – Parcurgerea entităților selectate
  – Parcurgerea unui subset de entități

• **Modificarea straturilor vectoriale**
  – Adăugarea entităților
  – Stergerea entităților
  – Modificarea entităților
  – Modificarea straturi vectoriale prin editarea unui tampon de memorie
  – Adăugarea și eliminarea câmpurilor

• **Crearea unui index spațial**

• **Creating Vector Layers**
  – *From an instance of* QgsVectorFileWriter
  – *Directly from features*
  – *From an instance of* QgsVectorLayer

• **Aspectul (simbologia) straturilor vectoriale**
  – Render cu Simbol Unic
  – Render cu Simboluri Categorisite
  – Render cu Simboluri Graduale
  – Lucrul cu Simboluri
    – **Lucrul cu Straturile Simbolului**
6.1 Retrieving information about attributes

You can retrieve information about the fields associated with a vector layer by calling `fields()` on a `QgsVectorLayer` object:

```python
vlayer = QgsVectorLayer("testdata/airports.shp", "airports", "ogr")
for field in vlayer.fields():
    print(field.name(), field.typeName())
```

```
ID Integer64
fk_region Integer64
ELEV Real
NAME String
USE String
```

The `displayField()` and `mapTipTemplate()` methods of the `QgsVectorLayer` class provide information on the field and template used in the map tips tab.

When you load a vector layer, a field is always chosen by QGIS as the Display Name, while the HTML Map Tip is empty by default. With these methods you can easily get both:

```python
vlayer = QgsVectorLayer("testdata/airports.shp", "airports", "ogr")
print(vlayer.displayField())
```

```
NAME
```

Note: If you change the Display Name from a field to an expression, you have to use `displayExpression()` instead of `displayField()`.

6.2 Iterating on vector layers

Iterating over the features in a vector layer is one of the most common tasks. Below is an example of the simple basic code to perform this task and showing some information about each feature. The `layer` variable is assumed to have a `QgsVectorLayer` object.

```python
# "layer" is a QgsVectorLayer instance
layer = iface.activeLayer()
features = layer.getFeatures()

for feature in features:
    # retrieve every feature with its geometry and attributes
    print("Feature ID: ", feature.id())
    # fetch geometry
    geom = feature.geometry()
    # show some information about the feature geometry
    geom = feature.geometry()
```

(continues on next page)
geomSingleType = QgsWkbTypes.isSingleType(geom.wkbType())

if geom.type() == QgsWkbTypes.PointGeometry:  
    # the geometry type can be of single or multi type
    if geomSingleType:
        x = geom.asPoint()
        print("Point: ", x)
    else:
        x = geom.asMultiPoint()
        print("MultiPoint: ", x)
elif geom.type() == QgsWkbTypes.LineGeometry:
    if geomSingleType:
        x = geom.asPolyline()
        print("Line: ", x, "length: ", geom.length())
    else:
        x = geom.asMultiPolyline()
        print("MultiLine: ", x, "length: ", geom.length())
elif geom.type() == QgsWkbTypes.PolygonGeometry:
    if geomSingleType:
        x = geom.asPolygon()
        print("Polygon: ", x, "Area: ", geom.area())
    else:
        x = geom.asMultiPolygon()
        print("MultiPolygon: ", x, "Area: ", geom.area())
else:
    print("Unknown or invalid geometry")

# fetch attributes
attrs = feature.attributes()
# attrs is a list. It contains all the attribute values of this feature
print(attrs)
# for this test only print the first feature
break

Feature ID:  1
Point:  <QgsPointXY: POINT(7 45)>
[1, 'First feature']

6.3 Selectarea entităților

In QGIS desktop, features can be selected in different ways: the user can click on a feature, draw a rectangle on
the map canvas or use an expression filter. Selected features are normally highlighted in a different color (default is
yellow) to draw user's attention on the selection.

Sometimes it can be useful to programmatically select features or to change the default color.

To select all the features, the selectAll() method can be used:

# Get the active layer (must be a vector layer)
layer = iface.activeLayer()
layer.selectAll()

To select using an expression, use the selectByExpression() method:

# Assumes that the active layer is points.shp file from the QGIS test suite
# (Class (string) and Heading (number) are attributes in points.shp)
layer = iface.activeLayer()
layer.selectByExpression(""Class"="B52" and "Heading" > 10 and "Heading" <70",
~QgsVectorLayer.SetSelection)
To change the selection color you can use `setSelectionColor()` method of `QgsMapCanvas` as shown in the following example:

```python
iface.mapCanvas().setSelectionColor(QColor("red"))
```

To add features to the selected features list for a given layer, you can call `select()` passing to it the list of features IDs:

```python
selected_fid = []

# Get the first feature id from the layer
for feature in layer.getFeatures():
    selected_fid.append(feature.id())
    break

# Add these features to the selected list
layer.select(selected_fid)
```

To clear the selection:

```python
layer.removeSelection()
```

### 6.3.1 Accesarea atributelor

Attributes can be referred to by their name:

```python
print(feature['name'])
```

First feature

Alternatively, attributes can be referred to by index. This is a bit faster than using the name. For example, to get the second attribute:

```python
print(feature[1])
```

First feature

### 6.3.2 Parcurgerea entităților selectate

If you only need selected features, you can use the `selectedFeatures()` method from the vector layer:

```python
selection = layer.selectedFeatures()
for feature in selection:
    # do whatever you need with the feature
    pass
```

### 6.3.3 Parcurgerea unui subset de entități

If you want to iterate over a given subset of features in a layer, such as those within a given area, you have to add a `QgsFeatureRequest` object to the `getFeatures()` call. Here’s an example:

```python
areaOfInterest = QgsRectangle(450290, 400520, 450750, 400780)
request = QgsFeatureRequest().setFilterRect(areaOfInterest)
for feature in layer.getFeatures(request):
    # do whatever you need with the feature
    pass
```
# do whatever you need with the feature
pass

For the sake of speed, the intersection is often done only using feature’s bounding box. There is however a flag `ExactIntersect` that makes sure that only intersecting features will be returned:

```python
request = QgsFeatureRequest().setFilterRect(areaOfInterest) \
    .setFlags(QgsFeatureRequest.ExactIntersect)
```

With `setLimit()` you can limit the number of requested features. Here’s an example:

```python
request = QgsFeatureRequest()
request.setLimit(2)
for feature in layer.getFeatures(request):
    print(feature)
```

If you need an attribute-based filter instead (or in addition) of a spatial one like shown in the examples above, you can build a `QgsExpression` object and pass it to the `QgsFeatureRequest` constructor. Here’s an example:

```python
# The expression will filter the features where the field "location_name"
# contains the word "Lake" (case insensitive)
exp = QgsExpression('"location_name" ILIKE "%Lake%"')
request = QgsFeatureRequest(exp)
```

See `Expresii, filtrarea si calculul valorilor` for the details about the syntax supported by `QgsExpression`.

Cererea poate fi utilizată pentru a defini datele cerute pentru fiecare entitate, astfel încât iteratorul să întoarcă toate entitățile, dar să returneze datele parțiale pentru fiecare dintre ele.

```python
# Only return selected fields to increase the "speed" of the request
request.setSubsetOfAttributes([0, 2])

# More user friendly version
request.setSubsetOfAttributes(["name","id"], layer.fields())

# Don’t return geometry objects to increase the "speed" of the request
request.setFlags(QgsFeatureRequest.NoGeometry)

# Fetch only the feature with id 45
request.setFilterFid(45)

# The options may be chained
request.setFilterRect(areaOfInterest).setFlags(QgsFeatureRequest.NoGeometry). 
    .setFilterFid(45).setSubsetOfAttributes([0, 2])
```

### 6.4 Modificarea straturilor vectoriale

Most vector data providers support editing of layer data. Sometimes they support just a subset of possible editing actions. Use the `capabilities()` function to find out what set of functionality is supported.

```python
caps = layer.dataProvider().capabilities()
# Check if a particular capability is supported:
if caps & QgsVectorDataProvider.DeleteFeatures:
    print("The layer supports DeleteFeatures")
```
The layer supports DeleteFeatures

For a list of all available capabilities, please refer to the API Documentation of QgsVectorDataProvider.

To print layer’s capabilities textual description in a comma separated list you can use capabilitiesString() as in the following example:

```python
1 caps_string = layer.dataProvider().capabilitiesString()
2 # Print:
3 # 'Add Features, Delete Features, Change Attribute Values, Add Attributes,
4 # Delete Attributes, Rename Attributes, Fast Access to Features at ID,
5 # Presimplify Geometries, Presimplify Geometries with Validity Check,
6 # Transactions, Curved Geometries'
```

Utilizând oricare dintre următoarele metode de editare a straturilor vectoriale, schimbările sunt efectuate direct în depozitul de date (un fisier, o baza de date etc). În cazul în care doriți să faceți doar schimbări temporare, treceți la secțiunea următoare, care explică efectuarea modifications with editing buffer.

Notă: If you are working inside QGIS (either from the console or from a plugin), it might be necessary to force a redraw of the map canvas in order to see the changes you’ve done to the geometry, to the style or to the attributes:

```python
1 # If caching is enabled, a simple canvas refresh might not be sufficient
2 # to trigger a redraw and you must clear the cached image for the layer
3 if iface.mapCanvas().isCachingEnabled():
4     layer.triggerRepaint()
5 else:
6     iface.mapCanvas().refresh()
```

### 6.4.1 Adăugarea entităților

Create some QgsFeature instances and pass a list of them to provider’s addFeatures() method. It will return two values: result (true/false) and list of added features (their ID is set by the data store).

To set up the attributes of the feature, you can either initialize the feature passing a QgsFields object (you can obtain that from the fields() method of the vector layer) or call initAttributes() passing the number of fields you want to be added.

```python
1 if caps & QgsVectorDataProvider.AddFeatures:
2     feat = QgsFeature(layer.fields())
3     feat.setAttributes([0, 'hello'])
4 # Or set a single attribute by key or by index:
5     feat.setAttribute('name', 'hello')
6     feat.setAttribute(0, 'hello')
7     feat.setGeometry(QgsGeometry.fromPointXY(QgsPointXY(123, 456)))
8     (res, outFeats) = layer.dataProvider().addFeatures([feat])
```
6.4.2 Ștergerea entităților

To delete some features, just provide a list of their feature IDs.

```python
if caps & QgsVectorDataProvider.DeleteFeatures:
    res = layer.dataProvider().deleteFeatures([5, 10])
```

6.4.3 Modificarea entităților

It is possible to either change feature’s geometry or to change some attributes. The following example first changes values of attributes with index 0 and 1, then it changes the feature’s geometry.

```python
fid = 100  # ID of the feature we will modify
if caps & QgsVectorDataProvider.ChangeAttributeValues:
    attrs = { 0 : "hello", 1 : 123 }
    layer.dataProvider().changeAttributeValues({ fid : attrs })
if caps & QgsVectorDataProvider.ChangeGeometries:
    geom = QgsGeometry.fromPointXY(QgsPointXY(111, 222))
    layer.dataProvider().changeGeometryValues({ fid : geom })
```

Sfat: Favor QgsVectorLayerEditUtils class for geometry-only edits

If you only need to change geometries, you might consider using the QgsVectorLayerEditUtils which provides some useful methods to edit geometries (translate, insert or move vertex, etc.).

6.4.4 Modificarea straturilor vectoriale prin editarea unui tampon de memorie

When editing vectors within QGIS application, you have to first start editing mode for a particular layer, then do some modifications and finally commit (or rollback) the changes. All the changes you make are not written until you commit them — they stay in layer’s in-memory editing buffer. It is possible to use this functionality also programmatically — it is just another method for vector layer editing that complements the direct usage of data providers. Use this option when providing some GUI tools for vector layer editing, since this will allow user to decide whether to commit/rollback and allows the usage of undo/redo. When changes are committed, all changes from the editing buffer are saved to data provider.

The methods are similar to the ones we have seen in the provider, but they are called on the QgsVectorLayer object instead.

For these methods to work, the layer must be in editing mode. To start the editing mode, use the startEditing() method. To stop editing, use the commitChanges() or rollBack() methods. The first one will commit all your changes to the data source, while the second one will discard them and will not modify the data source at all.

To find out whether a layer is in editing mode, use the isEditable() method.

Here you have some examples that demonstrate how to use these editing methods.

```python
from qgis.PyQt.QtCore import QVariant
feat1 = feat2 = QgsFeature(layer.fields())
fid = 99
feat1.setId(fid)
# add two features (QgsFeature instances)
layer.addFeatures([feat1,feat2])
# delete a feature with specified ID
layer.deleteFeature(fid)
```
In order to make undo/redo work properly, the above mentioned calls have to be wrapped into undo commands. (If you do not care about undo/redo and want to have the changes stored immediately, then you will have easier work by editing with data provider.)

Here is how you can use the undo functionality:

```python
layer.beginEditCommand("Feature triangulation")

# ... call layer's editing methods ...

if problem_occurred:
    layer.destroyEditCommand()
    # ... tell the user that there was a problem
    # and return

# ... more editing ...

layer.endEditCommand()
```

The `beginEditCommand()` method will create an internal „active” command and will record subsequent changes in vector layer. With the call to `endEditCommand()` the command is pushed onto the undo stack and the user will be able to undo/redo it from GUI. In case something went wrong while doing the changes, the `destroyEditCommand()` method will remove the command and rollback all changes done while this command was active.

De asemenea, puteți utiliza expresia `with edit(layer)` - pentru a încorpora într-un bloc de cod semantic, pentru commit și rollback, așa cum se arată în exemplul de mai jos:

```python
with edit(layer):
    feat = next(layer.getFeatures())
    feat[0] = 5
    layer.updateFeature(feat)
```

This will automatically call `commitChanges()` in the end. If any exception occurs, it will `rollBack()` all the changes. In case a problem is encountered within `commitChanges()` (when the method returns False) a `QgsEditError` exception will be raised.
6.4.5 Adăugarea și eliminarea câmpurilor

Pentru a adăuga câmpuri (atribute), trebuie să specificăm o listă de definitii pentru acestea. Pentru ștergerea de câmpuri e suficientă furnizarea unei liste de indecs pentru câmpuri.

```python
from qgis.PyQt.QtCore import QVariant

if caps & QgsVectorDataProvider.AddAttributes:
    res = layer.dataProvider().addAttributes([QgsField("mytext", QVariant.String),
                                              QgsField("myint", QVariant.Int)])
if caps & QgsVectorDataProvider.DeleteAttributes:
    res = layer.dataProvider().deleteAttributes([0])
```

După adăugarea sau eliminarea câmpurilor din furnizorul de date, câmpurile stratului trebuie să fie actualizate, deoarece modificările nu se propagă automat.

layer.updateFields()

**Sfat:** Direct save changes using with based command

Using with `edit(layer)`: the changes will be committed automatically calling `commitChanges()` at the end. If any exception occurs, it will `rollBack()` all the changes. See *Modificarea straturi vectoriale prin editarea unui tampon de memorie.*

6.5 Crearea unui index spațial

Indecșii spațiali pot îmbunătăți dramatic performanța codului dvs., în cazul în care este nevoie să interogați frecvent un strat vectorial. Imaginați-vă, de exemplu, că scrieți un algoritm de interpolare, și că, pentru o anumită locație, trebuie să aflați cele mai apropiate 10 puncte dintr-un strat, în scopul utilizării lor în calculul valorii interpolate. Fără un index spațial, singura modalitate pentru QGIS de a găsi cele 10 puncte este de a calcula distanța tuturor punctelor față de locația specificată și apoi de a compara aceste distanțe. Această sarcină poate fi mare consumatoare de timp, mai ales în cazul în care trebuie să fie repetată pentru mai multe locații. Dacă pentru stratul respectiv există un index spațial, operațiunea va fi mult mai eficientă.

Gândit-vă la un strat fără index spațial ca la o carte de telefon în care numerele de telefon nu sunt ordonate sau indexate. Singura modalitate de a afișa numărul de telefon al unei anumite persoane este de a citi toate numerele, începând cu primul, până când îl găsii.

Indecșii spațiali nu sunt creati în mod implicit pentru un strat QGIS vectorial, dar îi puteți genera cu ușurință. Iată ce trebuie să faceti:

- create spatial index using the `QgsSpatialIndex()` class:
• add features to index — index takes QgsFeature object and adds it to the internal data structure. You can create the object manually or use one from a previous call to the provider’s getFeatures() method.

index.addFeature(feat)

• alternatively, you can load all features of a layer at once using bulk loading

index = QgsSpatialIndex(layer.getFeatures())

• o dată ce ati introdus valori în indexul spatial, puteți efectua unele interogări

```python
# returns array of feature IDs of five nearest features
nearest = index.nearestNeighbor(QgsPointXY(25.4, 12.7), 5)

# returns array of IDs of features which intersect the rectangle
intersect = index.intersects(QgsRectangle(22.5, 15.3, 23.1, 17.2))
```

### 6.6 Creating Vector Layers

There are several ways to generate a vector layer dataset:

- the QgsVectorFileWriter class: A convenient class for writing vector files to disk, using either a static call to writeAsVectorFormat() which saves the whole vector layer or creating an instance of the class and issue calls to addFeature(). This class supports all the vector formats that OGR supports (GeoPackage, Shapefile, GeoJSON, KML and others).

- the QgsVectorLayer class: instantiates a data provider that interprets the supplied path (url) of the data source to connect to and access the data. It can be used to create temporary, memory-based layers (memory) and connect to OGR datasets (ogr), databases (postgres, spatialite, mysql, mssql) and more (wfs, gpx, delimitedtext...).

#### 6.6.1 From an instance of QgsVectorFileWriter

```python
# SaveVectorOptions contains many settings for the writer process
save_options = QgsVectorFileWriter.SaveVectorOptions()
transform_context = QgsProject.instance().transformContext()

# Write to a GeoPackage (default)
error = QgsVectorFileWriter.writeAsVectorFormatV2(layer,
                                                "testdata/my_new_file.gpkg",
                                                transform_context,
                                                save_options)

if error[0] == QgsVectorFileWriter.NoError:
    print("success!")
else:
    print(error)
```

```python
# Write to an ESRI Shapefile format dataset using UTF-8 text encoding
save_options = QgsVectorFileWriter.SaveVectorOptions()
save_options.driverName = "ESRI Shapefile"
save_options.fileEncoding = "UTF-8"

error = QgsVectorFileWriter.writeAsVectorFormatV2(layer,
                                                               "testdata/my_new_shapefile",
                                                               transform_context,
                                                               save_options)
```

(continues on next page)
if error[0] == QgsVectorFileWriter.NoError:
    print("success again!")
else:
    print(error)

# Write to an ESRI GDB file
save_options = QgsVectorFileWriter.SaveVectorOptions()
save_options.driverName = "FileGDB"
# if no geometry
save_options.overrideGeometryType = QgsWkbTypes.Unknown
save_options.actionOnExistingFile = QgsVectorFileWriter.CreateOrOverwriteLayer
save_options.layerName = "my_new_layer_name"
transform_context = QgsProject.instance().transformContext()
gdb_path = "testdata/my_example.gdb"
error = QgsVectorFileWriter.writeAsVectorFormatV2(layer,
            gdb_path,
            transform_context,
            save_options)
if error[0] == QgsVectorFileWriter.NoError:
    print("success!")
else:
    print(error)

You can also convert fields to make them compatible with different formats by using the `FieldValueConverter`. For example, to convert array variable types (e.g. in Postgres) to a text type, you can do the following:

```python
LIST_FIELD_NAME = 'xxxx'
class ESRIValueConverter(QgsVectorFileWriter.FieldValueConverter):
    def __init__(self, layer, list_field):
        QgsVectorFileWriter.FieldValueConverter.__init__(self)
        self.layer = layer
        self.list_field_idx = self.layer.fields().indexFromName(list_field)
    def convert(self, fieldIdxInLayer, value):
        if fieldIdxInLayer == self.list_field_idx:
            return QgsListFieldFormatter().representValue(layer=vlayer,
            fieldIndex=self.list_field_idx,
            config={},
            cache=None,
            value=value)
        else:
            return value
    def fieldDefinition(self, field):
        idx = self.layer.fields().indexFromName(field.name())
        if idx == self.list_field_idx:
            return QgsField(LIST_FIELD_NAME, QVariant.String)
        else:
            return self.layer.fields()[idx]
converter = ESRIValueConverter(vlayer, LIST_FIELD_NAME)
opts = QgsVectorFileWriter.SaveVectorOptions()
opts.fieldValueConverter = converter
```

A destination CRS may also be specified — if a valid instance of `QgsCoordinateReferenceSystem` is passed as the fourth parameter, the layer is transformed to that CRS.

For valid driver names please call the `supportedFiltersAndFormats` method or consult the supported formats by OGR — you should pass the value in the „Code“ column as the driver name.
Optionally you can set whether to export only selected features, pass further driver-specific options for creation or tell the writer not to create attributes… There are a number of other (optional) parameters; see the QgsVectorFileWriter documentation for details.

### 6.6.2 Directly from features

```python
from qgis.PyQt.QtCore import QVariant

# define fields for feature attributes. A QgsFields object is needed
fields = QgsFields()
fields.append(QgsField("first", QVariant.Int))
fields.append(QgsField("second", QVariant.String))

""" create an instance of vector file writer, which will create the vector file.
Arguments:
1. path to new file (will fail if exists already)
2. field map
3. geometry type - from WKBTYPE enum
4. layer's spatial reference (instance of QgsCoordinateReferenceSystem)
5. coordinate transform context
6. save options (driver name for the output file, encoding etc.)
"""

crs = QgsProject.instance().crs()
transform_context = QgsProject.instance().transformContext()
save_options = QgsVectorFileWriter.SaveVectorOptions()
save_options.driverName = "ESRI Shapefile"
save_options.fileEncoding = "UTF-8"

writer = QgsVectorFileWriter.create(
    "testdata/my_new_shapefile.shp",
    fields,
    QgsWkbTypes.Point,
    crs,
    transform_context,
    save_options
)

if writer.hasError() != QgsVectorFileWriter.NoError:
    print("Error when creating shapefile: ", writer.errorMessage())

# add a feature
fet = QgsFeature()
fet.setGeometry(QgsGeometry.fromPointXY(QgsPointXY(10,10)))
fet.setAttributes([1,"text"])
writer.addFeature(fet)

# delete the writer to flush features to disk
del writer
```
6.6.3 From an instance of QgsVectorLayer

Among all the data providers supported by the QgsVectorLayer class, let’s focus on the memory-based layers. Memory provider is intended to be used mainly by plugin or 3rd party app developers. It does not store data on disk, allowing developers to use it as a fast backend for some temporary layers.

Furnizorul suportă câmpuri de tip string, int sau double.

The memory provider also supports spatial indexing, which is enabled by calling the provider’s createSpatialIndex() function. Once the spatial index is created you will be able to iterate over features within smaller regions faster (since it’s not necessary to traverse all the features, only those in specified rectangle).

A memory provider is created by passing "memory" as the provider string to the QgsVectorLayer constructor.

The constructor also takes a URI defining the geometry type of the layer, one of: "Point", "LineString", "Polygon", "MultiPoint", "MultiLineString", "MultiPolygon" or "None".

URI poate specifica, de asemenea, sistemul de coordonate de referință, câmpurile, precum și indexarea furnizorului de memorie. Sintaxa este:

crs=definitie
index=yes
field=nume:tip(lungime,precizie)

În cele din urmă, să verificăm dacă totul a mers bine

```python
from qgis.PyQt.QtCore import QVariant

# create layer
vl = QgsVectorLayer("Point", "temporary_points", "memory")
pr = vl.dataProvider()

# add fields
pr.addAttributes([QgsField("name", QVariant.String),
                 QgsField("age", QVariant.Int),
                 QgsField("size", QVariant.Double)])
vl.updateFields()  # tell the vector layer to fetch changes from the provider

# add a feature
fet = QgsFeature()
fet.setGeometry(QgsGeometry.fromPointXY(QgsPointXY(10,10)))
fet.setAttributes(["Johny", 2, 0.3])
pr.addFeatures([fet])

# update layer’s extent when new features have been added
# because change of extent in provider is not propagated to the layer
vl.updateExtents()

# show some stats
print("fields:", len(pr.fields()))
print("features:", pr.featureCount())
e = vl.extent()
print("extent:", e.xMinimum(), e.yMinimum(), e.xMaximum(), e.yMaximum())

# iterate over features
```

(continues on next page)
features = vl.getFeatures()
for fet in features:
    print("F: ", fet.id(), fet.attributes(), fet.geometry().asPoint())

fields: 3
features: 1
extent: 10.0 10.0 10.0 10.0
F: 1 ['Johny', 2, 0.3] <QgsPointXY: POINT(10 10)>

6.7 Aspectul (simbologia) straturilor vectoriale

Când un strat vector este randat, aspectul datelor este dat de renderer și de simbolurile asociate stratului. Simbolurile sunt clase care au grijă de reprezentarea vizuală a tuturor entităților, în timp ce un render determină ce simbol va fi folosit doar pentru anumite entități.

The renderer for a given layer can be obtained as shown below:

renderer = layer.renderer()

Si cu acea referință, să explorăm un pic

print("Type: ", renderer.type())

Type: singleSymbol

There are several known renderer types available in the QGIS core library:

<table>
<thead>
<tr>
<th>Tipul</th>
<th>Clasa</th>
<th>Descrierea</th>
</tr>
</thead>
<tbody>
<tr>
<td>singleSymbol</td>
<td>QgsSingleSymbolRenderer</td>
<td>Asociază tuturor entităților același simbol</td>
</tr>
<tr>
<td>categorizedSymbol</td>
<td>QgsCategorizedSymbolRenderer</td>
<td>Asociază entităților un simbol diferit, în funcție de categorie</td>
</tr>
<tr>
<td>graduatedSymbol</td>
<td>QgsGraduatedSymbolRenderer</td>
<td>Asociază fiecărei entități un simbol diferit pentru fiecare gamă de valori</td>
</tr>
</tbody>
</table>

There might be also some custom renderer types, so never make an assumption there are just these types. You can query the application's QgsRendererRegistry to find out currently available renderers:

print(QgsApplication.rendererRegistry().renderersList())

['nullSymbol', 'singleSymbol', 'categorizedSymbol', 'graduatedSymbol',
 'RuleRenderer', 'pointDisplacement', 'pointCluster', 'invertedPolygonRenderer',
 'heatmapRenderer', '25dRenderer']

Este posibilă obținerea conținutului renderului sub formă de text — lucru util pentru depanare

renderer.dump()

SINGLE: MARKER SYMBOL (1 layers) color 190,207,80,255
6.7.1 Render cu Simbol Unic

You can get the symbol used for rendering by calling `symbol()` method and change it with `setSymbol()` method (note for C++ devs: the renderer takes ownership of the symbol.)

You can change the symbol used by a particular vector layer by calling `setSymbol()` passing an instance of the appropriate symbol instance. Symbols for point, line and polygon layers can be created by calling the `createSimple()` function of the corresponding classes `QgsMarkerSymbol`, `QgsLineSymbol` and `QgsFillSymbol`.

The dictionary passed to `createSimple()` sets the style properties of the symbol.

For example you can replace the symbol used by a particular point layer by calling `setSymbol()` passing an instance of a `QgsMarkerSymbol`, as in the following code example:

```python
symbol = QgsMarkerSymbol.createSimple({'name': 'square', 'color': 'red'})
layer.renderer().setSymbol(symbol)
# show the change
layer.triggerRepaint()
```

**nume**: indică forma markerului, aceasta putând fi oricare dintre următoarele:

- cerc
- pătrat
- cross
- dreptunghi
- diamant
- pentagon
- triunghi
- triunghi echilateral
- stea
- stea_regulată
- săgeată
- vârf_de_săgeată_plin
- x

To get the full list of properties for the first symbol layer of a symbol instance you can follow the example code:

```python
print(layer.renderer().symbol().symbolLayers()[0].properties())
```

This can be useful if you want to alter some properties:

```python
# You can alter a single property...
layer.renderer().symbol().symbolLayer(0).setSize(3)
# ... but not all properties are accessible from methods,
# you can also replace the symbol completely:
props = layer.renderer().symbol().symbolLayer(0).properties()
props['color'] = 'yellow'
props['name'] = 'square'
layer.renderer().setSymbol(QgsMarkerSymbol.createSimple(props))
```

(continues on next page)
6.7.2 Render cu Simboluri Categorisite

When using a categorized renderer, you can query and set the attribute that is used for classification: use the classAttribute() and setClassAttribute() methods.

Pentru a obține o listă de categori:

```python
categorized_renderer = QgsCategorizedSymbolRenderer()
# Add a few categories
cat1 = QgsRendererCategory('1', QgsMarkerSymbol(), 'category 1')
cat2 = QgsRendererCategory('2', QgsMarkerSymbol(), 'category 2')
categorized_renderer.addCategory(cat1)
categorized_renderer.addCategory(cat2)
for cat in categorized_renderer.categories():
    print("{}: {} :: ").format(cat.value(), cat.label(), cat.symbol()))
```

1: category 1 :: <qgis._core.QgsMarkerSymbol object at 0x7f8bad281b88>
2: category 2 :: <qgis._core.QgsMarkerSymbol object at 0x7f8bad281b88>

Where value() is the value used for discrimination between categories, label() is a text used for category description and symbol() method returns the assigned symbol.

The renderer usually stores also original symbol and color ramp which were used for the classification: sourceColorRamp() and sourceSymbol() methods.

6.7.3 Render cu Simboluri Graduale

Acest render este foarte similar cu renderul cu simbol clasificat, descris mai sus, dar în loc de o singură valoare de atribut per clasă el lucrează cu intervale de valori, putând fi, astfel, utilizat doar cu atribute numerice.

Pentru a afla mai multe despre gamele utilizate în render:

```python
graduated_renderer = QgsGraduatedSymbolRenderer()
# Add a few categories
graduated_renderer.addClassRange(QgsRendererRange(QgsClassificationRange('class 0-100', 0, 100), QgsMarkerSymbol()))
graduated_renderer.addClassRange(QgsRendererRange(QgsClassificationRange('class 101-200', 101, 200), QgsMarkerSymbol()))
for ran in graduated_renderer.ranges():
    print("{} - {}:").format(ran.lowerValue(), ran.upperValue(), ran.label(), ran.symbol())
```

0.0 - 100.0: class 0-100 <qgis._core.QgsMarkerSymbol object at 0x7f8bad281b88>
101.0 - 200.0: class 101-200 <qgis._core.QgsMarkerSymbol object at 0x7f8bad281b88>

you can again use the classAttribute (to find the classification attribute name), sourceSymbol and sourceColorRamp methods. Additionally there is the mode method which determines how the ranges were created: using equal intervals, quantiles or some other method.
Dacă doriți să creați propriul render cu simbol gradual, puteți face acest lucru așa cum este ilustrat în fragmentul de mai jos (care creează un simplu aranjament cu două clase)

```python
from qgis.PyQt.QtGui import QtGui

myVectorLayer = QgsVectorLayer("testdata/airports.shp", "airports", "ogr")
myTargetField = 'ELEV'
myRangeList = []
myOpacity = 1

# Make our first symbol and range...
myMin = 0.0
myMax = 50.0
myLabel = 'Group 1'
myColour = QtGui.QColor('#ffee00')
mySymbol1 = QgsSymbol.defaultSymbol(myVectorLayer.geometryType())
mySymbol1.setColor(myColour)
mySymbol1.setOpacity(myOpacity)
myRange1 = QgsRendererRange(myMin, myMax, mySymbol1, myLabel)
myRangeList.append(myRange1)

#now make another symbol and range...
myMin = 50.1
myMax = 100
myLabel = 'Group 2'
myColour = QtGui.QColor('#00eff')
mySymbol2 = QgsSymbol.defaultSymbol(myVectorLayer.geometryType())
mySymbol2.setColor(myColour)
mySymbol2.setOpacity(myOpacity)
myRange2 = QgsRendererRange(myMin, myMax, mySymbol2, myLabel)
myRangeList.append(myRange2)

myRenderer = QgsGraduatedSymbolRenderer('airports', myRangeList)
myClassificationMethod = QgsApplication.classificationMethodRegistry().method("EqualInterval")
myRenderer.setClassificationMethod(myClassificationMethod)
myRenderer.setClassAttribute(myTargetField)

myVectorLayer.setRenderer(myRenderer)
```

6.7.4 Lucrul cu Simboluri

For representation of symbols, there is QgsSymbol base class with three derived classes:

- **QgsMarkerSymbol** — for point features
- **QgsLineSymbol** — for line features
- **QgsFillSymbol** — for polygon features

*Every symbol consists of one or more symbol layers* (classes derived from QgsSymbolLayer). The symbol layers do the actual rendering, the symbol class itself serves only as a container for the symbol layers.

Having an instance of a symbol (e.g. from a renderer), it is possible to explore it: the *type* method says whether it is a marker, line or fill symbol. There is a *dump* method which returns a brief description of the symbol. To get a list of symbol layers:

```python
marker_symbol = QgsMarkerSymbol()
for i in range(marker_symbol.symbolLayerCount()):
    lyr = marker_symbol.symbolLayer(i)
    print("{:>2}: {}").format(i, lyr.layerType()))
```

0: SimpleMarker

6.7. Aspectul (simbologia) straturilor vectoriale
To find out symbol’s color use `color` method and `setColor` to change its color. With marker symbols additionally you can query for the symbol size and rotation with the `size` and `angle` methods. For line symbols the `width` method returns the line width.

Dimensiunea și lățimea sunt în milimetri, în mod implicit, iar unghiurile sunt în grade.

**Lucrul cu Straturile Simbolului**

As said before, symbol layers (subclasses of `QgsSymbolLayer`) determine the appearance of the features. There are several basic symbol layer classes for general use. It is possible to implement new symbol layer types and thus arbitrarily customize how features will be rendered. The `layerType()` method uniquely identifies the symbol layer class — the basic and default ones are `SimpleMarker`, `SimpleLine` and `SimpleFill` symbol layers types.

You can get a complete list of the types of symbol layers you can create for a given symbol layer class with the following code:

```python
from qgis.core import QgsSymbolLayerRegistry
myRegistry = QgsApplication.symbolLayerRegistry()
myMetadata = myRegistry.symbolLayerMetadata("SimpleFill")
for item in myRegistry.symbolLayersForType(QgsSymbol.Marker):
    print(item)
```

The `QgsSymbolLayerRegistry` class manages a database of all available symbol layer types.

To access symbol layer data, use its `properties()` method that returns a key-value dictionary of properties which determine the appearance. Each symbol layer type has a specific set of properties that it uses. Additionally, there are the generic methods `color`, `size`, `angle` and `width`, with their setter counterparts. Of course size and angle are available only for marker symbol layers and width for line symbol layers.

**Crearea unor Tipuri Personalizate de Straturi pentru Simboluri**

Imaginați-vă că ați dori să personalizați modul în care se randează datele. Vă puteți crea propria dvs. clasă de strat de simbol, care va desena entitățile exact așa cum doriti. Iată un exemplu de marker care desenează cercuri roșii cu o rază specificată:

```python
from qgis.core import QgsMarkerSymbolLayer
from qgis.PyQt.QtGui import QColor

class FooSymbolLayer(QgsMarkerSymbolLayer):
    def __init__(self, radius=4.0):
        QgsMarkerSymbolLayer.__init__(self)
        self.radius = radius
        self.color = QColor(255, 0, 0)

    def layerType(self):
        return "FooMarker"

    def properties(self):
        return { "radius" : str(self.radius) }
```

(continues on next page)
The `layerType` method determines the name of the symbol layer; it has to be unique among all symbol layers. The `properties` method is used for persistence of attributes. The `clone` method must return a copy of the symbol layer with all attributes being exactly the same. Finally there are rendering methods: `startRender` is called before rendering the first feature, `stopRender` when the rendering is done, and `renderPoint` is called to do the rendering. The coordinates of the point(s) are already transformed to the output coordinates.

For polylines and polygons the only difference would be in the rendering method: you would use `renderPolyline` which receives a list of lines, while `renderPolygon` receives a list of points on the outer ring as the first parameter and a list of inner rings (or None) as a second parameter.

De obicei, este convenabilă adăugarea unui GUI pentru setarea atributelor tipului de strat pentru simboluri, pentru a permite utilizatorilor să personalizeze aspectul: în exemplul de mai sus, putem lasa utilizatorul să seteze raza cercului.

```python
from qgis.gui import QgsSymbolLayerWidget

class FooSymbolLayerWidget(QgsSymbolLayerWidget):
    def __init__(self, parent=None):
        QgsSymbolLayerWidget.__init__(self, parent)

        self.layer = None

        # setup a simple UI
        self.label = QLabel("Radius:"
        self.spinRadius = QDoubleSpinBox()
        self.hbox = QHBoxLayout()
        self.hbox.addWidget(self.label)
        self.hbox.addWidget(self.spinRadius)
        self.setLayout(self.hbox)
        self.connect(self.spinRadius, SIGNAL("valueChanged(double)"), \
                     self.radiusChanged)

    def setSymbolLayer(self, layer):
        if layer.layerType() != "FooMarker":
            return
        self.layer = layer
        self.spinRadius.setValue(layer.radius)

    def symbolLayer(self):
        return self.layer

    def radiusChanged(self, value):
        self.layer.radius = value
        self.emit(SIGNAL("changed()"))
```

6.7. Aspectul (simbologia) straturilor vectoriale
This widget can be embedded into the symbol properties dialog. When the symbol layer type is selected in symbol properties dialog, it creates an instance of the symbol layer and an instance of the symbol layer widget. Then it calls the setSymbolLayer method to assign the symbol layer to the widget. In that method the widget should update the UI to reflect the attributes of the symbol layer. The symbolLayer method is used to retrieve the symbol layer again by the properties dialog to use it for the symbol.

On every change of attributes, the widget should emit the changed() signal to let the properties dialog update the symbol preview.

Acum mai lipsește doar liantul final: pentru a face QGIS consistent de aceste noi clase. Acest lucru se face prin adăugarea stratului simbol la registru. Este posibilă utilizarea stratului simbol, de asemenea, fără a-l adăuga la registru, dar unele funcționalități nu vor fi disponibile: de exemplu, încărcarea de fisiere de proiect cu straturi simbol personalizate sau incapacitatea de a editatributele stratului în GUI.

Va trebui să creăm metadate pentru stratul simbolului

```python
from qgis.core import QgsSymbol, QgsSymbolLayerAbstractMetadata,
    QgsSymbolLayerRegistry

class FooSymbolLayerMetadata(QgsSymbolLayerAbstractMetadata):
    def __init__(self):
        super().__init__("FooMarker", "My new Foo marker", QgsSymbol.Marker)

    def createSymbolLayer(self, props):
        radius = float(props["radius"]) if "radius" in props else 4.0
        return FooSymbolLayer(radius)

QgsApplication.symbolLayerRegistry().addSymbolLayerType(FooSymbolLayerMetadata())
```

You should pass layer type (the same as returned by the layer) and symbol type (marker/line/fill) to the constructor of the parent class. The createSymbolLayer() method takes care of creating an instance of symbol layer with attributes specified in the props dictionary. And there is the createSymbolLayerWidget() method which returns the settings widget for this symbol layer type.

Ultimul pas este de a adăuga acest strat simbol la registru — și am încheiat.

### 6.7.5 Crearea renderelor Personalizate

Ar putea fi utilă crearea unei noi implementări de render, dacă doriti să personalizați regulile de selectare a simbolurilor pentru randarea entităților. Unele cazuri de utilizare: simbolul să fie determinat de o combinație de câmpuri, dimensiunea simbolurilor să depindă de scara curentă, etc.

Următorul cod prezintă o simplă randare personalizată, care creează două simboluri de tip marker și apoi alege aleatoriu unul dintre ele pentru fiecare entitate

```python
import random
from qgis.core import QgsWkbTypes, QgsSymbol, QgsFeatureRenderer

class RandomRenderer(QgsFeatureRenderer):
    def __init__(self, syms=None):
        super().__init__("RandomRenderer")
        self.syms = syms if syms else [
            QgsSymbol.defaultSymbol(QgsWkbTypes.geometryType(QgsWkbTypes.Point)),
            QgsSymbol.defaultSymbol(QgsWkbTypes.geometryType(QgsWkbTypes.Point))
        ]

    def symbolForFeature(self, feature, context):
        return random.choice(self.syms)

    def startRender(self, context, fields):
```

The constructor of the parent `QgsFeatureRenderer` class needs a renderer name (which has to be unique among renderers). The `symbolForFeature` method is the one that decides what symbol will be used for a particular feature. `startRender` and `stopRender` take care of initialization/finalization of symbol rendering. The `usedAttributes` method can return a list of field names that the renderer expects to be present. Finally, the `clone` method should return a copy of the renderer.

Like with symbol layers, it is possible to attach a GUI for configuration of the renderer. It has to be derived from `QgsRendererWidget`. The following sample code creates a button that allows the user to set the first symbol.

```python
from qgis.gui import QgsRendererWidget, QgsColorButton

class RandomRendererWidget(QgsRendererWidget):
    def __init__(self, layer, style, renderer):
        super().__init__(layer, style)
        if renderer is None or renderer.type() != "RandomRenderer":
            self.r = RandomRenderer()
        else:
            self.r = renderer
        # setup UI
        self.btn1 = QgsColorButton()
        self.btn1.setColor(self.r.syms[0].color())
        self.vbox = QVBoxLayout()
        self.vbox.addWidget(self.btn1)
        self.setLayout(self.vbox)
        self.btn1.colorChanged.connect(self.setColor1)

    def setColor1(self):
        color = self.btn1.color()
        if not color.isValid(): return
        self.r.syms[0].setColor(color)

    def renderer(self):
        return self.r
```

The constructor receives instances of the active layer (`QgsVectorLayer`), the global style (`QgsStyle`) and the current renderer. If there is no renderer or the renderer has different type, it will be replaced with our new renderer, otherwise we will use the current renderer (which has already the type we need). The widget contents should be updated to show current state of the renderer. When the renderer dialog is accepted, the widget's `renderer` method is called to get the current renderer — it will be assigned to the layer.

Ultimul bit lipsă este cel al metadatelor renderului și înregistrarea în registru, altfel încărcarea straturilor cu renderul nu va funcționa, iar utilizatorul nu va fi capabil să-l selecteze din lista de rendere. Să finalizăm exemplul nostru de `RandomRenderer`.

6.7. Aspectul (simbologia) straturilor vectoriale
from qgis.core import  
QgsRendererAbstractMetadata,  
QgsRendererRegistry,  
QgsApplication
)

class RandomRendererMetadata(QgsRendererAbstractMetadata):
    def __init__(self):
        super().__init__("RandomRenderer", "Random renderer")
    def createRenderer(self, element):
        return RandomRenderer()
    def createRendererWidget(self, layer, style, renderer):
        return RandomRendererWidget(layer, style, renderer)
QgsApplication.rendererRegistry().addRenderer(RandomRendererMetadata())

Similarly as with symbol layers, abstract metadata constructor awaits renderer name, name visible for users and
optionally name of renderer’s icon. The createRenderer method passes a QDomElement instance that can
be used to restore the renderer’s state from the DOM tree. The createRendererWidget method creates the
configuration widget. It does not have to be present or can return None if the renderer does not come with GUI.

To associate an icon with the renderer you can assign it in the QgsRendererAbstractMetadata constructor as
a third (optional) argument — the base class constructor in the RandomRendererMetadata__init__() function
becomes

QgsRendererAbstractMetadata.__init__(self,  
"RandomRenderer",  
"Random renderer",  
QIcon(QPixmap("RandomRendererIcon.png", "png")))

The icon can also be associated at any later time using the setIcon method of the metadata class. The icon can be
loaded from a file (as shown above) or can be loaded from a Qt resource (PyQt5 includes .qrc compiler for Python).

6.8 Lecturi suplimentare

DE EFECTUAT:
  • creating/modifying symbols
  • working with style (QgsStyle)
  • working with color ramps (QgsColorRamp)
  • exploring symbol layer and renderer registries

The code snippets on this page need the following imports if you’re outside the pyqgis console:

from qgis.core import  
QgsGeometry,  
QgsPoint,  
QgsPointXY,  
QgsWkbTypes,  
QgsProject,  
QgsFeatureRequest,  
QgsVectorLayer,  
QgsDistanceArea,  
QgsUnitTypes,  
)
Manipularea geometriei

Points, linestrings and polygons that represent a spatial feature are commonly referred to as geometries. In QGIS they are represented with the *QgsGeometry* class.

Uneori, o geometrie poate fi de fapt o colecție de simple geometrii (simple-părți). O astfel de geometrie poartă denumirea de geometrie multi-parte. În cazul în care conține doar un singur tip de geometrie simplă, o numeim multi-punct, multi-linie sau multi-poligon. De exemplu, o țară formată din mai multe insule poate fi reprezentată ca un multi-poligon.

Coordonatele geometriilor pot fi în orice sistem de coordonate de referință (CRS). Când extragem entitățile dintr-un strat, geometriile asociate vor avea coordonatele în CRS-ul stratului.

Description and specifications of all possible geometries construction and relationships are available in the [OGC Simple Feature Access Standards](https://www.opengeospatial.org/standards/sfa) for advanced details.

### 7.1 Construirea geometriei

PyQGIS provides several options for creating a geometry:

- din coordonate

```python
1 gpnt = QgsGeometry.fromPointXY(QgsPointXY(1, 1))
2 print(gpnt)
3 gLine = QgsGeometry.fromPolyline([QgsPoint(1, 1), QgsPoint(2, 2)])
4 print(gLine)
5 gPolygon = QgsGeometry.fromPolygonXY([[QgsPointXY(1, 1),
   QgsPointXY(2, 2), QgsPointXY(2, 1)]]
6 print(gPolygon)
```

Coordinates are given using *QgsPoint* class or *QgsPointXY* class. The difference between these classes is that *QgsPoint* supports M and Z dimensions.
A Polyline (Linestring) is represented by a list of points.

A Polygon is represented by a list of linear rings (i.e. closed linestrings). The first ring is the outer ring (boundary), optional subsequent rings are holes in the polygon. Note that unlike some programs, QGIS will close the ring for you so there is no need to duplicate the first point as the last.

Geometriile multi-parte merg cu un nivel mai departe: multi-punctele sunt o listă de puncte, multi-liniile o listă de linii iar multi-poligoanele sunt o listă de poligoane.

• din well-known text (WKT)

```python
geom = QgsGeometry.fromWkt("POINT(3 4)")
print(geom)
```

• din well-known binary (WKB)

```python
g = QgsGeometry()
wkb = bytes.fromhex("010100000000000000000045400000000000000001440")
g.fromWkb(wkb)

# print WKT representation of the geometry
print(g.asWkt())
```

### 7.2 Accesarea geometriei

First, you should find out the geometry type. The `wkbType()` method is the one to use. It returns a value from the `QgsWkbTypes.Type` enumeration.

```python
if gPnt.wkbType() == QgsWkbTypes.Point:
    print(gPnt.wkbType())
# output: 1 for Point
if gLine.wkbType() == QgsWkbTypes.LineString:
    print(gLine.wkbType())
# output: 2 for LineString
if gPolygon.wkbType() == QgsWkbTypes.Polygon:
    print(gPolygon.wkbType())
# output: 3 for Polygon
```

As an alternative, one can use the `type()` method which returns a value from the `QgsWkbTypes.GeometryType` enumeration.

You can use the `displayString()` function to get a human readable geometry type.

```python
print(QgsWkbTypes.displayString(gPnt.wkbType()))
# output: 'Point'
pdint(QgsWkbTypes.displayString(gLine.wkbType()))
# output: 'LineString'
pdint(QgsWkbTypes.displayString(gPolygon.wkbType()))
# output: 'Polygon'
```

Point
LineString
Polygon

There is also a helper function `isMultipart()` to find out whether a geometry is multipart or not.

To extract information from a geometry there are accessor functions for every vector type. Here’s an example on how to use these accessors:
print (gPnt.asPoint())
# output: QgsPointXY: POINT(1 1)
print (gLine.asPolyline())
# output: [QgsPointXY: POINT(1 1), QgsPointXY: POINT(2 2)]
print (gPolygon.asPolygon())
# output: [[QgsPointXY: POINT(1 1), QgsPointXY: POINT(2 2), QgsPointXY:...
# POINT(2 1), QgsPointXY: POINT(1 1)]

Nota: The tuples (x,y) are not real tuples, they are QgsPoint objects, the values are accessible with x() and y() methods.

For multipart geometries there are similar accessor functions: asMultiPoint(), asMultiPolyline() and asMultiPolygon().

7.3 Predicate și operațiuni geometrice

QGIS uses GEOS library for advanced geometry operations such as geometry predicates (contains(), intersects(), ...) and set operations (combine(), difference(), ...). It can also compute geometric properties of geometries, such as area (in the case of polygons) or lengths (for polygons and lines).

Let’s see an example that combines iterating over the features in a given layer and performing some geometric computations based on their geometries. The below code will compute and print the area and perimeter of each country in the countries layer within our tutorial QGIS project.

The following code assumes layer is a QgsVectorLayer object that has Polygon feature type.

```
# let's access the 'countries' layer
layer = QgsProject.instance().mapLayersByName('countries')[0]

# let's filter for countries that begin with Z, then get their features
query = "name LIKE 'Zu%'
features = layer.getFeatures(QgsFeatureRequest().setFilterExpression(query))

# now loop through the features, perform geometry computation and print the results
for f in features:
    geom = f.geometry()
    name = f.attribute('NAME')
    print(name)
    print('Area: ', geom.area())
    print('Perimeter: ', geom.length())
```

Zubin Potok
Area: 0.040717371293465573
Perimeter: 0.9406133328077781
Zulia
Area: 3.708060762610232
Perimeter: 17.172123598311487
Zuid-Holland
Area: 0.4204687950359031
Perimeter: 4.098878517120812
Zug
Area: 0.027573510374275363
Perimeter: 0.7756605461489624

Now you have calculated and printed the areas and perimeters of the geometries. You may however quickly notice that the values are strange. That is because areas and perimeters don’t take CRS into account when computed using the area() and length() methods from the QgsGeometry class. For a more powerful area and distance calculation, the QgsDistanceArea class can be used, which can perform ellipsoid based calculations:

7.3. Predicate și operațiuni geometrice
The following code assumes `layer` is a `QgsVectorLayer` object that has Polygon feature type.

```python
# Distance and area using the QgsDistanceArea class

d = QgsDistanceArea()
d.setEllipsoid('WGS84')

layer = QgsProject.instance().mapLayersByName('countries')[0]

# let's filter for countries that begin with Z, then get their features
query = "name" LIKE '%Zu%'
features = layer.getFeatures(QgsFeatureRequest().setFilterExpression(query))

for f in features:
    geom = f.geometry()
    name = f.attribute('NAME')
    print("Perimeter (m): ", d.measurePerimeter(geom))
    print("Area (m2): ", d.measureArea(geom))

    # let's calculate and print the area again, but this time in square kilometers
    print("Area (km2): ", d.convertAreaMeasurement(d.measureArea(geom), QgsUnitTypes.AreaSquareKilometers))
```

```
Zubin Potok
Perimeter (m): 87581.40256396442
Area (m2): 369302069.18814206
Area (km2): 369.30206918814207
Zulia
Perimeter (m): 189122.70945423362
Area (m2): 44973645460.19726
Area (km2): 44973.64546019726
Zuid-Holland
Perimeter (m): 331941.8000214341
Area (m2): 232457391.52097562
Area (km2): 232.45739152097562
```

Alternatively, you may want to know the distance and bearing between two points.

```
# Let's create two points.
# Santa claus is a workaholic and needs a summer break,
# let's see how far is Tenerife from his home
santa = QgsPointXY(25.847899, 66.543456)
tenerife = QgsPointXY(-16.5735, 28.0443)

print("Distance in meters: ", d.measureLine(santa, tenerife))
```

Puteți căuta mai multe exemple de algoritmi care sunt incluși în QGIS și să folosiți aceste metode pentru a analiza și a transforma datele vectoriale. Mai jos sunt prezente câteva trimiteri spre codul unora dintre ele.

- **Distance and area using the QgsDistanceArea class:** Distance matrix algorithm
- **Lines to polygons algorithm**

The code snippets on this page need the following imports if you’re outside the pyqgis console:

```python
from qgis.core import (QgsCoordinateReferenceSystem,
                        
(continues on next page)
```
7.3. Predicate și operațiuni geometrice

QgsCoordinateTransform,
QgsProject,
QgsPointXY,
}
8.1 Sisteme de coordonate de referință

Coordinate reference systems (CRS) are encapsulated by the QgsCoordinateReferenceSystem class. Instances of this class can be created in several different ways:

- specifică CRS-ul după ID-ul său

```python
# EPSG 4326 is allocated for WGS84
crs = QgsCoordinateReferenceSystem("EPSG:4326")
assert crs.isValid()
```

QGIS supports different CRS identifiers with the following formats:

- EPSG:<code> — ID assigned by the EPSG organization - handled with `createFromOgcWms()`
- POSTGIS:<srid> — ID used in PostGIS databases - handled with `createFromSrid()`
- INTERNAL:<srsid> — ID used in the internal QGIS database - handled with `createFromSr-sid()`
- PROJ:<proj> - handled with `createFromProj()`
- WKT:<wkt> - handled with `createFromWkt()`

If no prefix is specified, WKT definition is assumed.

- specifică CRS-ul prin well-known text (WKT)

```python
wkt = 'GEOGCS["WGS84", DATUM["WGS84", SPHEROID["WGS84", 6378137.0, 298.257232656]],]' \\
    'PRIMEM["Greenwich", 0.0], UNIT["degree", 0.017453292519943295],]' \\
    'AXIS["Longitude", EAST], AXIS["Latitude", NORTH])'
crs = QgsCoordinateReferenceSystem(wkt)
assert crs.isValid()
```

- create an invalid CRS and then use one of the `create*` functions to initialize it. In the following example we use a Proj string to initialize the projection.

```python
crs = QgsCoordinateReferenceSystem()
crs.createFromProj("+proj=longlat +ellps=WGS84 +datum=WGS84 +no_defs")
assert crs.isValid()
```
It's wise to check whether creation (i.e. lookup in the database) of the CRS has been successful: `isValid()` must return `True`.

Note that for initialization of spatial reference systems QGIS needs to look up appropriate values in its internal database `srs.db`. Thus in case you create an independent application you need to set paths correctly with `QgsApplication.setPrefixPath()`, otherwise it will fail to find the database. If you are running the commands from the QGIS Python console or developing a plugin you do not care: everything is already set up for you.

Accessing spatial reference system information:

```python
crs = QgsCoordinateReferenceSystem("EPSG:4326")
print("QGIS CRS ID: ", crs.srsid())
print("PostGIS SRID: ", crs.postgisSrid())
print("Description: ", crs.description())
print("Projection Acronym: ", crs.projectionAcronym())
print("Ellipsoid Acronym: ", crs.ellipsoidAcronym())
print("Proj String: ", crs.toProj())
# check whether it's geographic or projected coordinate system
print("Is geographic: ", crs.isGeographic())
# check type of map units in this CRS (values defined in Qgis::units enum)
print("Map units: ", crs.mapUnits())
```

Output:

<table>
<thead>
<tr>
<th>QGIS CRS ID: 3452</th>
</tr>
</thead>
<tbody>
<tr>
<td>PostGIS SRID: 4326</td>
</tr>
<tr>
<td>Description: WGS 84</td>
</tr>
<tr>
<td>Projection Acronym: longlat</td>
</tr>
<tr>
<td>Ellipsoid Acronym: WGS84</td>
</tr>
<tr>
<td>Proj String: +proj=longlat +datum=WGS84 +no_defs</td>
</tr>
<tr>
<td>Is geographic: True</td>
</tr>
<tr>
<td>Map units: 6</td>
</tr>
</tbody>
</table>

### 8.2 CRS Transformation

You can do transformation between different spatial reference systems by using the `QgsCoordinateTransform` class. The easiest way to use it is to create a source and destination CRS and construct a `QgsCoordinateTransform` instance with them and the current project. Then just repeatedly call `transform()` function to do the transformation. By default it does forward transformation, but it is capable to do also inverse transformation.

```python
crsSrc = QgsCoordinateReferenceSystem("EPSG:4326")  # WGS 84
crsDest = QgsCoordinateReferenceSystem("EPSG:32633")  # WGS 84 / UTM zone 33N
transformContext = QgsProject.instance().transformContext()
xform = QgsCoordinateTransform(crsSrc, crsDest, transformContext)

# forward transformation: src -> dest
pt1 = xform.transform(QgsPointXY(18, 5))
print("Transformed point: ", pt1)

# inverse transformation: dest -> src
pt2 = xform.transform(pt1, QgsCoordinateTransform.ReverseTransform)
print("Transformed back: ", pt2)
```

Output:

Transformed point: <QgsPointXY: POINT(832713.79873844375833869 553423.98688333143945783)>
Transformed back: <QgsPointXY: POINT(18 5)>

Capitolul 8. Proiecții suportate
The code snippets on this page need the following imports if you’re outside the pyqgis console:

```
from qgis.PyQt.QtGui import (QtColor,)
from qgis.PyQt.QtCore import Qt, QRectF
from qgis.core import (QgsVectorLayer,
                         QgsPoint,
                         QgsPointXY,
                         QgsProject,
                         QgsGeometry,
                         QgsMapRendererJob,
                         )
from qgis.gui import (QgsMapCanvas,
                       QgsVertexMarker,
                       QgsMapCanvasItem,
                       QgsRubberBand,
                       )
```

8.2. CRS Transformation
Using the Map Canvas

• Încapsularea suportului de hârtă
• Benzile elastice și marcajele nodurilor
• Folosirea instrumentelor în suportul de hârtă
• Dezvoltarea instrumentelor personalizate pentru suportul de hârtă
• Dezvoltarea elementelor personalizate pentru suportul de hârtă

The Map canvas widget is probably the most important widget within QGIS because it shows the map composed from overlaid map layers and allows interaction with the map and layers. The canvas always shows a part of the map defined by the current canvas extent. The interaction is done through the use of map tools: there are tools for panning, zooming, identifying layers, measuring, vector editing and others. Similar to other graphics programs, there is always one tool active and the user can switch between the available tools.

The map canvas is implemented with the QgsMapCanvas class in the qgis.gui module. The implementation is based on the Qt Graphics View framework. This framework generally provides a surface and a view where custom graphics items are placed and user can interact with them. We will assume that you are familiar enough with Qt to understand the concepts of the graphics scene, view and items. If not, please read the overview of the framework.

Whenever the map has been panned, zoomed in/out (or some other action that triggers a refresh), the map is rendered again within the current extent. The layers are rendered to an image (using the QgsMapRendererJob class) and that image is displayed on the canvas. The QgsMapCanvas class also controls refreshing of the rendered map. Besides this item which acts as a background, there may be more map canvas items.

Typical map canvas items are rubber bands (used for measuring, vector editing etc.) or vertex markers. The canvas items are usually used to give visual feedback for map tools, for example, when creating a new polygon, the map tool creates a rubber band canvas item that shows the current shape of the polygon. All map canvas items are subclasses of QgsMapCanvasItem which adds some more functionality to the basic QGraphicsItem objects.

Pentru a rezuma, arhitectura suportului pentru hârtă constă în trei concepte:

• suportul de hârtă — pentru vizualizarea hârtiilor
• map canvas items — additional items that can be displayed on the map canvas
• map tools — for interaction with the map canvas
9.1 Încapsularea suportului de hartă

Map canvas is a widget like any other Qt widget, so using it is as simple as creating and showing it.

```python
canvas = QgsMapCanvas()
canvas.show()
```

This produces a standalone window with map canvas. It can be also embedded into an existing widget or window. When using .ui files and Qt Designer, place a QWidget on the form and promote it to a new class: set QgsMapCanvas as class name and set qgis.gui as header file. The pyuic5 utility will take care of it. This is a very convenient way of embedding the canvas. The other possibility is to manually write the code to construct map canvas and other widgets (as children of a main window or dialog) and create a layout.

În mod implicit, canevasul hărții are un fundal negru și nu utilizează anti-zimtare. Pentru a seta fundalul alb și pentru a permite anti-zimtare pentru o redare mai bună:

```python
canvas.setCanvasColor(Qt.white)
canvas.enableAntiAliasing(True)
```

(In case you are wondering, Qt comes from PyQt.QtCore module and Qt.white is one of the predefined QColor instances.)

Now it is time to add some map layers. We will first open a layer and add it to the current project. Then we will set the canvas extent and set the list of layers for the canvas.

```python
vlayer = QgsVectorLayer('testdata/airports.shp', 'Airports layer', 'ogr')
if not vlayer.isValid():
    print("Layer failed to load!")

# add layer to the registry
QgsProject.instance().addMapLayer(vlayer)

# set extent to the extent of our layer
canvas.setExtent(vlayer.extent())

# set the map canvas layer set
canvas.setLayers([vlayer])
```

După executarea acestor comenzi, suportul ar trebui să arate stratul pe care le-ați încărcat.

9.2 Benzile elastice și marcajele nodurilor

To show some additional data on top of the map in canvas, use map canvas items. It is possible to create custom canvas item classes (covered below), however there are two useful canvas item classes for convenience: QgsRubberBand for drawing polylines or polygons, and QgsVertexMarker for drawing points. They both work with map coordinates, so the shape is moved/scaled automatically when the canvas is being panned or zoomed.

To show a polyline:

```python
r = QgsRubberBand(canvas, False)  # False = not a polygon
points = [QgsPoint(-100, 45), QgsPoint(10, 60), QgsPoint(120, 45)]
r.setToGeometry(QgsGeometry.fromPolyline(points), None)
```

Pentru a afișa un poligon

```python
r = QgsRubberBand(canvas, True)  # True = a polygon
points = [[QgsPointXY(-100, 35), QgsPointXY(10, 50), QgsPointXY(120, 35)]]
r.setToGeometry(QgsGeometry.fromPolygonXY(points), None)
```
Retineți că punctele pentru poligon nu reprezintă o simplă listă: în fapt, aceasta este o listă de inele conținând inele liniare ale poligonului: primul inel reprezintă granița externă, în plus (optional) inelele corespund găurilor din poligon.

Benzile elastice acceptă unele personalizări, și anume schimbarea culorii și a lățimii liniei:

```python
r.setColor(QColor(0, 0, 255))
r.setWidth(3)
```

The canvas items are bound to the canvas scene. To temporarily hide them (and show them again), use the `hide()` and `show()` combo. To completely remove the item, you have to remove it from the scene of the canvas:

```python
canvas.scene().removeItem(r)
```

(În C++ este posibilă ștergerea doar a elementului, însă în Python `del r` ar șterge doar referința iar obiectul va exista în continuare, acesta fiind deținut de suport)

Rubber band can be also used for drawing points, but the `QgsVertexMarker` class is better suited for this (`QgsRubberBand` would only draw a rectangle around the desired point).

You can use the vertex marker like this:

```python
m = QgsVertexMarker(canvas)
m.setCenter(QgsPointXY(10, 40))
m.setColor(QColor(0, 255, 0))
m.setIconSize(5)
m.setIconType(QgsVertexMarker.ICON_BOX) # or ICON_CROSS, ICON_X
m.setPenWidth(3)
```

For temporary hiding of vertex markers and removing them from canvas, use the same methods as for rubber bands.

### 9.3 Folosirea instrumentelor în suportul de hartă

The following example constructs a window that contains a map canvas and basic map tools for map panning and zooming. Actions are created for activation of each tool: panning is done with `QgsMapToolPan`, zooming in/out with a pair of `QgsMapToolZoom` instances. The actions are set as checkable and later assigned to the tools to allow automatic handling of checked/unchecked state of the actions – when a map tool gets activated, its action is marked as selected and the action of the previous map tool is deselected. The map tools are activated using `setMapTool()` method.

```python
from qgis.gui import *
from qgis.PyQt.QtWidgets import QAction, QMainWindow
from qgis.PyQt.QtCore import Qt

class MyWnd(QMainWindow):
    def __init__(self, layer):
        super(MyWnd, self).__init__(self)

        self.canvas = QgsMapCanvas()
        self.canvas.setCanvasColor(Qt.white)
        self.canvas.setExtent(layer.extent())
        self.canvas.setLayers([layer])

        self.setCentralWidget(self.canvas)
        self.actionZoomIn = QAction("Zoom in", self)
```
You can try the above code in the Python console editor. To invoke the canvas window, add the following lines to instantiate the MyWnd class. They will render the currently selected layer on the newly created canvas:

```python
w = MyWnd(iface.activeLayer())
w.show()
```

### 9.4 Dezvoltarea instrumentelor personalizate pentru suportul de hartă

You can write your custom tools, to implement a custom behavior to actions performed by users on the canvas.

Map tools should inherit from the `QgsMapTool` class or any derived class, and selected as active tools in the canvas using the `setMapTool()` method as we have already seen.

Iată un exemplu de instrument pentru hartă, care permite definirea unei limite dreptunghiulare, făcând clic și trăgând cursorul mouse-ului pe canevas. După ce este definit dreptunghiul, coordonatele sale sunt afișate în consolă. Se utilizează elementele benzii elastice descrise mai înainte, pentru a arăta dreptunghiul selectat, așa cum a fost definit.

```python
class RectangleMapTool(QgsMapToolEmitPoint):
    def __init__(self, canvas):
        self.canvas = canvas
        QgsMapToolEmitPoint.__init__(self, self.canvas)
        self.rubberBand = QgsRubberBand(self.canvas, True)

    def zoomIn(self):
        self.canvas.setMapTool(self.toolZoomIn)

def zoomOut(self):
    self.canvas.setMapTool(self.toolZoomOut)

def pan(self):
    self.canvas.setMapTool(self.toolPan)

# create the map tools
self.toolPan = QgsMapToolPan(self.canvas)
self.toolPan.setAction(self.actionPan)
self.toolZoomIn = QgsMapToolZoom(self.canvas, False)  # false = in
self.toolZoomIn.setAction(self.actionZoomIn)
self.toolZoomOut = QgsMapToolZoom(self.canvas, True)   # true = out
self.toolZoomOut.setAction(self.actionZoomOut)
```

The code above would allow you to create a custom tool for drawing rectangles on the map canvas. After defining the rectangle, its coordinates would be displayed in the console. You can try this in the Python console editor by following the provided steps.
self.rubberBand.setColor(Qt.red)
self.rubberBand.setWidth(1)
self.reset()

def reset(self):
    self.startPoint = self.endPoint = None
    self.isEmittingPoint = False
    self.rubberBand.reset(True)

def canvasPressEvent(self, e):
    self.startPoint = self.toMapCoordinates(e.pos())
    self.endPoint = self.startPoint
    self.isEmittingPoint = True
    self.showRect(self.startPoint, self.endPoint)

def canvasMoveEvent(self, e):
    if not self.isEmittingPoint:
        return
    self.endPoint = self.toMapCoordinates(e.pos())
    self.showRect(self.startPoint, self.endPoint)

def showRect(self, startPoint, endPoint):
    self.rubberBand.reset(QGis.Polygon)
    if startPoint.x() == endPoint.x() or startPoint.y() == endPoint.y():
        return
    point1 = QgsPoint(startPoint.x(), startPoint.y())
    point2 = QgsPoint(startPoint.x(), endPoint.y())
    point3 = QgsPoint(endPoint.x(), endPoint.y())
    point4 = QgsPoint(endPoint.x(), startPoint.y())
    self.rubberBand.addPoint(point1, False)
    self.rubberBand.addPoint(point2, False)
    self.rubberBand.addPoint(point3, False)
    self.rubberBand.addPoint(point4, True)  # true to update canvas
    self.rubberBand.show()

def rectangle(self):
    if self.startPoint is None or self.endPoint is None:
        return None
    elif (self.startPoint.x() == self.endPoint.x() or \
          self.startPoint.y() == self.endPoint.y()):
        return None
    return QgsRectangle(self.startPoint, self.endPoint)

def deactivate(self):
    QgsMapTool.deactivate(self)
    self.deactivated.emit()
Here is an example of a custom canvas item that draws a circle:

```python
class CircleCanvasItem(QgsMapCanvasItem):
    def __init__(self, canvas):
        super().__init__(canvas)
        self.center = QgsPoint(0, 0)
        self.size = 100

    def setCenter(self, center):
        self.center = center

    def center(self):
        return self.center

    def setSize(self, size):
        self.size = size

    def size(self):
        return self.size

    def boundingRect(self):
        return QRectF(self.center.x() - self.size/2,
                      self.center.y() - self.size/2,
                      self.center.x() + self.size/2,
                      self.center.y() + self.size/2)

    def paint(self, painter, option, widget):
        path = QPainterPath()
        path.moveTo(self.center.x(), self.center.y());
        path.arcTo(self.boundingRect(), 0.0, 360.0)
        painter.fillPath(path, QColor("red"))

# Using the custom item:
item = CircleCanvasItem(iface.mapCanvas())
item.setCenter(QgsPointXY(200,200))
item.setSize(80)
```

The code snippets on this page need the following imports:

```python
import os

from qgis.core import 
    QgsGeometry,
    QgsMapSettings,
    QgsPrintLayout,
    QgsMapSettings,
    QgsMapRendererParallelJob,
    QgsLayoutItemLabel,
    QgsLayoutItemLegend,
    QgsLayoutItemMap,
    QgsLayoutItemPolygon,
    QgsLayoutItemScaleBar,
    QgsLayoutExporter,
    QgsLayoutItem,
    QgsLayoutPoint,
    QgsLayoutSize,
    QgsUnitTypes,
```

(continues on next page)
from qgis.PyQt.QtGui import (QPolygonF, QColor,
)

from qgis.PyQt.QtCore import (QPointF, QRectF, QSize,
)
Randarea hărților și imprimarea

There are generally two approaches when input data should be rendered as a map: either do it quick way using QgsMapRendererJob or produce more fine-tuned output by composing the map with the QgsLayout class.

10.1 Randarea simplă

The rendering is done creating a QgsMapSettings object to define the rendering settings, and then constructing a QgsMapRendererJob with those settings. The latter is then used to create the resulting image.

Iată un exemplu:

```python
image_location = os.path.join(QgsProject.instance().homePath(), "render.png")
vlayer = iface.activeLayer()
settings = QgsMapSettings()
settings.setLayers([vlayer])
settings.setBackgroundColor(QColor(255, 255, 255))
settings.setOutputSize(QSize(800, 600))
settings.setExtent(vlayer.extent())
render = QgsMapRendererParallelJob(settings)

def finished():
    img = render.renderedImage()
    # save the image; e.g. img.save("/Users/myuser/render.png","png")
    img.save(image_location, "png")
```

(continues on next page)
17 render.finished.connect(finished)
18 render.start()

10.2 Randarea straturilor cu diferite CRS-uri

If you have more than one layer and they have a different CRS, the simple example above will probably not work: to get the right values from the extent calculations you have to explicitly set the destination CRS

```python
layers = [iface.activeLayer()]
settings.setLayers(layers)
settings.setDestinationCrs(layers[0].crs())
```

10.3 Output using print layout

Print layout is a very handy tool if you would like to do a more sophisticated output than the simple rendering shown above. It is possible to create complex map layouts consisting of map views, labels, legend, tables and other elements that are usually present on paper maps. The layouts can be then exported to PDF, raster images or directly printed on a printer.

The layout consists of a bunch of classes. They all belong to the core library. QGIS application has a convenient GUI for placement of the elements, though it is not available in the GUI library. If you are not familiar with Qt Graphics View framework, then you are encouraged to check the documentation now, because the layout is based on it.

The central class of the layout is the `QgsLayout` class, which is derived from the Qt `QGraphicsScene` class. Let us create an instance of it:

```python
project = QgsProject()
lAYOUT = QgsPrintLayout(project)
lAYOUT.initializeDefaults()
```

Now we can add various elements (map, label, ...) to the layout. All these objects are represented by classes that inherit from the base `QgsLayoutItem` class.

Here’s a description of some of the main layout items that can be added to a layout.

- **harta** — acest element indică bibliotecilor unde să pună harta. Vom crea o hartă și o vom întinde peste întreaga dimensiune a hârtiei

  ```python
  map = QgsLayoutItemMap(lAYOUT)
lAYOUT.addItem(map)
  ```

- **eticheta** — permite afișarea textelor. Este posibilă modificarea fontului, culoarea, alinierea și marginea

  ```python
  label = QgsLayoutItemLabel(lAYOUT)
  label.setText("Hello world")
lable.adjustSizeToText()
lAYOUT.addItem(label)
  ```

- **legenda**

  ```python
  legend = QgsLayoutItemLegend(lAYOUT)
  legend.setLinkedMap(map)  # map is an instance of QgsLayoutItemMap
  lAYOUT.addItem(legend)
  ```

- **scara grafică**
item = QgsLayoutItemScaleBar(layout)
item.setStyle('Numeric')  # optionally modify the style
item.setLinkedMap(map)  # map is an instance of QgsLayoutItemMap
item.applyDefaultSize()
layout.addItem(item)

• sâgeată
• imagine
• basic shape
• nodes based shape

polygon = QPolygonF()
polygon.append(QPointF(0.0, 0.0))
polygon.append(QPointF(100.0, 0.0))
polygon.append(QPointF(200.0, 100.0))
polygon.append(QPointF(100.0, 200.0))
polygonItem = QgsLayoutItemPolygon(polygon, layout)
layout.addItem(polygonItem)

props = {}
props["color"] = "green"
props["style"] = "solid"
props["style_border"] = "solid"
props["color_border"] = "black"
props["width_border"] = "10.0"
props["joinstyle"] = "miter"
symbol = QgsFillSymbol.createSimple(props)
polygonItem.setSymbol(symbol)

• tabelă

Once an item is added to the layout, it can be moved and resized:

item.attemptMove(QgsLayoutPoint(1.4, 1.8, QgsUnitTypes.LayoutCentimeters))
item.attemptResize(QgsLayoutSize(2.8, 2.2, QgsUnitTypes.LayoutCentimeters))

A frame is drawn around each item by default. You can remove it as follows:

# for a composer label
label.setFrameEnabled(False)

Besides creating the layout items by hand, QGIS has support for layout templates which are essentially compositions with all their items saved to a .qpt file (with XML syntax).

Once the composition is ready (the layout items have been created and added to the composition), we can proceed to produce a raster and/or vector output.

10.3. Output using print layout
10.3.1 Exporting the layout

To export a layout, the `QgsLayoutExporter` class must be used.

```python
base_path = os.path.join(QgsProject.instance().homePath())
pdf_path = os.path.join(base_path, "output.pdf")
exporter = QgsLayoutExporter(layout)
exporter.exportToPdf(pdf_path, QgsLayoutExporter.PdfExportSettings())
```

Use the `exportToImage()` in case you want to export to an image instead of a PDF file.

10.3.2 Exporting a layout atlas

If you want to export all pages from a layout that has the atlas option configured and enabled, you need to use the `atlas()` method in the exporter (`QgsLayoutExporter`) with small adjustments. In the following example, the pages are exported to PNG images:

```python
exporter.exportToImage(layout.atlas(), base_path, 'png', QgsLayoutExporter.ImageExportSettings())
```

Notice that the outputs will be saved in the base path folder, using the output filename expression configured on atlas.

The code snippets on this page need the following imports if you’re outside the pyqgis console:

```python
from qgis.core import (edit,
QgsExpression,
QgsExpressionContext,
QgsFeature,
QgsFeatureRequest,
QgsField,
QgsFields,
QgsVectorLayer,
QgsPointXY,
QgsGeometry,
QgsProject,
QgsExpressionContextUtils
)
```
Expresii, filtrarea și calculul valorilor

- **Parsarea expresiilor**
- **Evaluarea expresiilor**
  - Expresii de bază
  - Expresii cu entități
  - Filtering a layer with expressions
- **Handling expression errors**

QGIS are un oarecare suport pentru analiza expresiilor, cum ar fi SQL. Doar un mic subset al sintaxei SQL este acceptat. Expresiile pot fi evaluate fie ca predicate booleene (returnând True sau False), fie ca funcții (care întorc o valoare scalară). Parcurgeți vector_expressions din Manualul Utilizatorului, pentru o listă completă a funcțiilor disponibile.

Trei tipuri de bază sunt acceptate:

- — număr atât numere întregi cât și numere zecimale, de exemplu, 123, 3.14
- șir — acesta trebuie să fie cuprins între ghilimele simple: 'hello world'
- referință către coloană — atunci când se evaluatează, referința este substituită cu valoarea reală a câmpului. Numele nu sunt protejate.

Următoarele operațiuni sunt disponibile:

- operatori aritmetici: +, −, *, /, ^
- paranteze: pentru forțarea priorității operatorului: (1 + 1) * 3
- plus și minus unari: -12, +5
- funcții matematice: sqrt, sin, cos, tan, asin, acos, atan
- funcții de conversie: to_int, to_real, to_string, to_date
- funcții geometrice: $area, $length
- funcții de manipulare a geometriei: $x, $y, $geometry, num_geometries, centroid

Și următoarele predicate sunt suportate:
comparatie: =, !=, >, >=, <, <=
potrivirea paternurilor: LIKE (folosind % și _), ~ (expresii regulate)
predicate logice: AND, OR, NOT
verificarea valorii NULL: IS NULL, IS NOT NULL

Exemple de predicate:
- 1 + 2 = 3
- \( \sin(\text{angle}) > 0 \)
- 'Hello' LIKE 'He%'
- \((x > 10 \text{ AND } y > 10) \text{ OR } z = 0\)

Exemple de expresii scalare:
- \(2^10\)
- \(\sqrt{\text{val}}\)
- \($\text{length} + 1\)

11.1 Parsarea expresiilor

The following example shows how to check if a given expression can be parsed correctly:

```
exp = QgsExpression('1 + 1 = 2')
assert(not exp.hasParserError())

exp = QgsExpression('1 + 1 = ')
assert(exp.hasParserError())

assert(exp.parserErrorString() == '\nsyntax error, unexpected $end')
```

11.2 Evaluarea expresiilor

Expressions can be used in different contexts, for example to filter features or to compute new field values. In any case, the expression has to be evaluated. That means that its value is computed by performing the specified computational steps, which can range from simple arithmetic to aggregate expressions.

11.2.1 Expresii de bază

This basic expression evaluates to 1, meaning it is true:

```
exp = QgsExpression('1 + 1 = 2')
assert(exp.evaluate()) # exp.evaluate() returns 1 and assert() recognizes this as True
```
11.2.2 Expresii cu entități

To evaluate an expression against a feature, a QgsExpressionContext object has to be created and passed to the evaluate function in order to allow the expression to access the feature’s field values.

The following example shows how to create a feature with a field called „Column” and how to add this feature to the expression context.

```python
fields = QgsFields()
field = QgsField('Column')
fields.append(field)
feature = QgsFeature()
feature.setFields(fields)
feature.setAttribute(0, 99)
exp = QgsExpression('"Column"')
context = QgsExpressionContext()
context.setFeature(feature)
assert (exp.evaluate(context) == 99)
```

The following is a more complete example of how to use expressions in the context of a vector layer, in order to compute new field values:

```python
from qgis.PyQt.QtCore import QVariant

# create a vector layer
vl = QgsVectorLayer("Point", "Companies", "memory")
pr = vl.dataProvider()
pr.addAttributes([QgsField("Name", QVariant.String),
                  QgsField("Employees", QVariant.Int),
                  QgsField("Revenue", QVariant.Double),
                  QgsField("Rev. per employee", QVariant.Double),
                  QgsField("Sum", QVariant.Double),
                  QgsField("Fun", QVariant.Double)])
vl.updateFields()

# add data to the first three fields
my_data = [
    {'x': 0, 'y': 0, 'name': 'ABC', 'emp': 10, 'rev': 100.1},
    {'x': 1, 'y': 1, 'name': 'DEF', 'emp': 2, 'rev': 50.5},
    {'x': 5, 'y': 5, 'name': 'GHI', 'emp': 100, 'rev': 725.9}]

for rec in my_data:
    f = QgsFeature()
    pt = QgsPointXY(rec['x'], rec['y'])
    f.setGeometry(QgsGeometry.fromPointXY(pt))
    f.setAttributes([rec['name'], rec['emp'], rec['rev']])
    pr.addFeature(f)
vl.updateExtents()
QgsProject.instance().addMapLayer(vl)

# The first expression computes the revenue per employee.
# The second one computes the sum of all revenue values in the layer.
# The final third expression doesn't really make sense but illustrates
# the fact that we can use a wide range of expression functions, such
# as area and buffer in our expressions:
expression1 = QgsExpression("Revenue/"Employees")
expression2 = QgsExpression("sum("Revenue")")
expression3 = QgsExpression("area(buffer($geometry,"Employees")")
```

(continues on next page)
# function that adds the global, project, and layer scopes all at once.
# Alternatively, those scopes can also be added manually. In any case,
# it is important to always go from "most generic" to "most specific"
# scope, i.e. from global to project to layer
context = QgsExpressionContext()
context.appendScopes(QgsExpressionContextUtils.globalProjectLayerScopes(vl))

with edit(vl):
    for f in vl.getFeatures():
        context.setFeature(f)
        f['Rev. per employee'] = expression1.evaluate(context)
        f['Sum'] = expression2.evaluate(context)
        f['Fun'] = expression3.evaluate(context)
    vl.updateFeature(f)

print(f['Sum'])

876.5

11.2.3 Filtering a layer with expressions

Următorul exemplu poate fi folosit pentru a filtra un strat și pentru a întoarce orice entitate care se potrivesc unui predicat.

layer = QgsVectorLayer("Point?field=Test:integer",
"addfeat", "memory")
layer.startEditing()
for i in range(10):
    feature = QgsFeature()
    feature.setAttributes([i])
    assert(layer.addFeature(feature))
layer.commitChanges()

expression = 'Test >= 3'
request = QgsFeatureRequest().setFilterExpression(expression)
matches = 0
for f in layer.getFeatures(request):
    matches += 1
assert(matches == 7)

11.3 Handling expression errors

Expression-related errors can occur during expression parsing or evaluation:

exp = QgsExpression("1 + 1 = 2")
if exp.hasParserError():
    raise Exception(exp.parserErrorString())
value = exp.evaluate()
if exp.hasEvalError():
    raise ValueError(exp.evalErrorString())

The code snippets on this page need the following imports if you’re outside the pyqgis console:
from qgis.core import (QgsProject,
QgsSettings,
QgsVectorLayer
)
Capitolul 11. Expresii, filtrarea și calculul valorilor
De multe ori, pentru un plugin, este utilă salvarea unor variabile, astfel încât utilizatorul să nu trebuiască să le reintruducă sau să le reselecteze, la fiecare rulare a plugin-ului.

Aceste variabile pot fi salvate cu ajutorul 

Qt și QGIS API. Pentru fiecare variabilă ar trebui să alegi o cheie care va fi folosită pentru a accesa variabila — pentru culoarea preferată a utilizatorului aţi putea folosi o cheie de genul „culoare_favorită” sau orice alt sir semnificativ. Este recomandabil să folosiți o oarecare logică în denumirea cheilor.

We can differentiate between several types of settings:

• **global settings** — they are bound to the user at a particular machine. QGIS itself stores a lot of global settings, for example, main window size or default snapping tolerance. Settings are handled using the QgsSettings class, through for example the setValue() and value() methods.

Here you can see an example of how these methods are used.

```python
def store():
    s = QgsSettings()
    s.setValue("myplugin/mytext", "hello world")
    s.setValue("myplugin/myint", 10)
    s.setValue("myplugin/myreal", 3.14)

def read():
    s = QgsSettings()
    mytext = s.value("myplugin/mytext", "default text")
    myint = s.value("myplugin/myint", 123)
    myreal = s.value("myplugin/myreal", 2.71)
    nonexistent = s.value("myplugin/nonexistent", None)
    print(mytext)
    print(myint)
    print(myreal)
    print(nonexistent)
```

The second parameter of the value() method is optional and specifies the default value that is returned if there is no previous value set for the passed setting name.

For a method to pre-configure the default values of the global settings through the global_settings.ini file, see deploying_organization for further details.

• **project settings** — vary between different projects and therefore they are connected with a project file. Map canvas background color or destination coordinate reference system (CRS) are examples — white background
and WGS84 might be suitable for one project, while yellow background and UTM projection are better for another one.

An example of usage follows.

```python
proj = QgsProject.instance()

# store values
proj.writeEntry("myplugin", "mytext", "hello world")
proj.writeEntry("myplugin", "myint", 10)
proj.writeEntry("myplugin", "mydouble", 0.01)
proj.writeEntry("myplugin", "mybool", True)

# read values (returns a tuple with the value, and a status boolean
# which communicates whether the value retrieved could be converted
to its type, in these cases a string, an integer, a double and a boolean
# respectively)
mytext, type_conversion_ok = proj.readEntry("myplugin",
                                           "mytext",
                                           "default text")
myint, type_conversion_ok = proj.readNumEntry("myplugin",
                                           "myint",
                                           123)
mydouble, type_conversion_ok = proj.readDoubleEntry("myplugin",
                                           "mydouble",
                                           123)
mybool, type_conversion_ok = proj.readBoolEntry("myplugin",
                                           "mybool",
                                           123)
```

As you can see, the `writeEntry()` method is used for all data types, but several methods exist for reading the setting value back, and the corresponding one has to be selected for each data type.

- **map layer settings** — these settings are related to a particular instance of a map layer with a project. They are not connected with underlying data source of a layer, so if you create two map layer instances of one shapefile, they will not share the settings. The settings are stored inside the project file, so if the user opens the project again, the layer-related settings will be there again. The value for a given setting is retrieved using the `customProperty()` method, and can be set using the `setCustomProperty()` one.

```python
vlayer = QgsVectorLayer()

# save a value
vlayer.setCustomProperty("mytext", "hello world")

# read the value again (returning "default text" if not found)
mytext = vlayer.customProperty("mytext", "default text")
```

The code snippets on this page need the following imports if you’re outside the pyqgis console:

```python
from qgis.core import 
    QgsMessageLog,
    QgsGeometry,
)

from qgis.gui import 
    QgsMessageBar,
)

from qgis.PyQt.QtWidgets import 
    QSizePolicy,
    QPushButton,
    QDialog,
    QGridLayout,
(continues on next page)
```
QDialogButtonBox,
CAPITOLUL 13

Comunicarea cu utilizatorul

Această secțiune prezintă câteva metode și elemente care ar trebui să fie utilizate pentru a comunica cu utilizatorul, în scopul menținerii coerentei interfaței cu utilizatorul.

13.1 Showing messages. The QgsMessageBar class

Folosirea casetelor de mesaje poate fi o idee rea, din punctul de vedere al experienței utilizatorului. Pentru a arăta o mică linie de informații sau un mesaj de avertizare/eroare, bara QGIS de mesaje este, de obicei, o opțiune mai bună.

Folosind referința către obiectul interfaței QGIS, puteți afișa un text în bara de mesaje, cu ajutorul următorului cod:

```python
from qgis.core import Qgis
iface.messageBar().pushMessage("Error", "I'm sorry Dave, I'm afraid I can't do that ~", level=Qgis.Critical)
```

Messages(2): Error : I'm sorry Dave, I'm afraid I can't do that

![Fig. 13.1: Bara de mesaje a QGIS](image-url)

Puteți seta o durată, pentru afișarea pentru o perioadă limitată de timp.
iface.messageBar().pushMessage("Ooops", "The plugin is not working as it should", level=Qgis.Critical, duration=3)

Messages(2): Ooops : The plugin is not working as it should

Fig. 13.2: Bara de mesaje a QGIS, cu cronometru

The examples above show an error bar, but the level parameter can be used to creating warning messages or info messages, using the Qgis.MessageLevel enumeration. You can use up to 4 different levels:

0. Info
1. Warning
2. Critical
3. Success

Fig. 13.3: Bara de mesaje a QGIS (info)

Widget-urile pot fi adăugate la bara de mesaje, cum ar fi, de exemplu, un buton pentru afișarea mai multor informații

```python
def showError():
    pass

widget = iface.messageBar().createMessage("Missing Layers", "Show Me")
button = QPushButton(widget)
button.setText("Show Me")
button.pressed.connect(showError)
widget.layout().addWidget(button)
iface.messageBar().pushWidget(widget, Qgis.Warning)
```

Messages(1): Missing Layers : Show Me

Fig. 13.4: Bara de mesaje a QGIS, cu un buton

Puteți utiliza o bară de mesaje chiar și în propria fereastră de dialog, în loc să apelați la o casetă de text, sau să arătați mesajul în fereastra principală a QGIS
class MyDialog(QDialog):
    def __init__(self):
        QDialog.__init__(self)
        self.bar = QgsMessageBar()
        self.bar.setSizePolicy(QSizePolicy.Minimum, QSizePolicy.Fixed)
        self.setLayout(QGridLayout())
        self.layout().setContentsMargins(0, 0, 0)
        self.buttonbox = QDialogButtonBox(QDialogButtonBox.Ok)
        self.buttonbox.accepted.connect(self.run)
        self.layout().addWidget(self.buttonbox, 0, 0, 2, 1)
        self.layout().addWidget(self.bar, 0, 0, 1, 1)

    def run(self):
        self.bar.pushMessage("Hello", "World", level=Qgis.Info)

myDlg = MyDialog()
myDlg.show()
13.2 Afisarea progresului

Barele de progres pot fi, de asemenea, incluse în bara de mesaje QGIS, din moment ce, așa cum am văzut, aceasta acceptă widget-urile. Iată un exemplu pe care îl puteți încerca în consolă.

```python
import time
from qgis.PyQt.QtWidgets import QProgressBar
from qgis.PyQt.QtCore import *

progressMessageBar = iface.messageBar().createMessage("Doing something boring...")
progress = QProgressBar()
progress.setMaximum(10)
progress.setAlignment(Qt.AlignLeft | Qt.AlignVCenter)
progressMessageBar.layout().addWidget(progress)
iface.messageBar().pushWidget(progressMessageBar, Qgis.Info)

for i in range(10):
    time.sleep(1)
    progress.setValue(i + 1)
iface.messageBar().clearWidgets()
```

Messages(0): Doing something boring...

Also, you can use the built-in status bar to report progress, as in the next example:

```python
vlayer = iface.activeLayer()
count = vlayer.featureCount()
features = vlayer.getFeatures()

for i, feature in enumerate(features):
    # do something time-consuming here
    print('.') # printing should give enough time to present the progress
    percent = i / float(count) * 100
   iface.mainWindow().statusBar().showMessage("Processed {} %".format(int(percent)));
iface.statusBarIface().showMessage("Processed {} %".format(int(percent)))
iface.statusBarIface().clearMessage()
```

13.3 Jurnalizare

There are three different types of logging available in QGIS to log and save all the information about the execution of your code. Each has its specific output location. Please consider to use the correct way of logging for your purpose:

- **QgsMessageLog** is for messages to communicate issues to the user. The output of the QgsMessageLog is shown in the Log Messages Panel.
- The python built in logging module is for debugging on the level of the QGIS Python API (PyQGIS). It is recommended for Python script developers that need to debug their python code, e.g. feature ids or geometries
- **QgsLogger** is for messages for QGIS internal debugging / developers (i.e. you suspect something is triggered by some broken code). Messages are only visible with developer versions of QGIS.

Examples for the different logging types are shown in the following sections below.
Atentionare: Use of the Python `print` statement is unsafe to do in any code which may be multithreaded and extremely slows down the algorithm. This includes expression functions, renderers, symbol layers and Processing algorithms (amongst others). In these cases you should always use the python logging module or thread safe classes (`QgsLogger` or `QgsMessageLog`) instead.

13.3.1 QgsMessageLog

```python
# You can optionally pass a 'tag' and a 'level' parameters
QgsMessageLog.logMessage("Your plugin code has been executed correctly", 'MyPlugin --', level=Qgis.Info)
QgsMessageLog.logMessage("Your plugin code might have some problems", level=Qgis.Warning)
QgsMessageLog.logMessage("Your plugin code has crashed!", level=Qgis.Critical)
```

MyPlugin:0) Your plugin code has been executed correctly
(1): Your plugin code might have some problems
(2): Your plugin code has crashed!

Nota: You can see the output of the `QgsMessageLog` in the log_message_panel

13.3.2 The python built in logging module

```python
import logging
formatter = '%(asctime)s - %(name)s - %(levelname)s - %(message)s'
logfilename=r'c:\temp\example.log'
logging.basicConfig(filename=logfilename, level=logging.DEBUG, format=formatter)
logging.info("This logging info text goes into the file")
logging.debug("This logging debug text goes into the file as well")
```

The basicConfig method configures the basic setup of the logging. In the above code the filename, logging level and the format are defined. The filename refers to where to write the logfile to, the logging level defines what levels to output and the format defines the format in which each message is output.

```
2020-10-08 13:14:42,998 - root - INFO - This logging text goes into the file
2020-10-08 13:14:42,998 - root - DEBUG - This logging debug text goes into the file as well
```

If you want to erase the log file every time you execute your script you can do something like:

```python
if os.path.isfile(logfilename):
    with open(logfilename, 'w') as file:
        pass
```

Further resources on how to use the python logging facility are available at:

- https://docs.python.org/3/library/logging.html
- https://docs.python.org/3/howto/logging.html
- https://docs.python.org/3/howto/logging-cookbook.html

Atentionare: Please note that without logging to a file by setting a filename the logging may be multithreaded which heavily slows down the output.
The code snippets on this page need the following imports if you’re outside the pyqgis console:

```python
from qgis.core import (QgsApplication, QgsRasterLayer, QgsAuthMethodConfig, QgsDataSourceUri, QgsPkiBundle, QgsMessageLog,)

from qgis.gui import (QgsAuthAuthoritiesEditor, QgsAuthConfigEditor, QgsAuthConfigSelect, QgsAuthSettingsWidget,)

from qgis.QtWidgets import (QWidget, QTabWidget,)

from qgis.QtNetwork import QSslCertificate
```
Infrastructura de autentificare

    - PKI examples with other data providers
- Adapt plugins to use Authentication infrastructure
- Authentication GUIs
  - GUI to select credentials
  - Authentication Editor GUI
  - Authorities Editor GUI
14.1 Introducere

Referința utilizatorului pentru infrastructura de autentificare se găsește în Manualul Utilizatorului, în paragraful authentication_overview.

Acest capitol descrie cele mai bune practici de utilizare, din perspectiva dezvoltatorului, a Sistemului de Autentificare. The authentication system is widely used in QGIS Desktop by data providers whenever credentials are required to access a particular resource, for example when a layer establishes a connection to a Postgres database.

There are also a few widgets in the QGIS gui library that plugin developers can use to easily integrate the authentication infrastructure into their code:

- QgsAuthConfigEditor
- QgsAuthConfigSelect
- QgsAuthSettingsWidget

A good code reference can be read from the authentication infrastructure tests code.

Atenționare: Due to the security constraints that were taken into account during the authentication infrastructure design, only a selected subset of the internal methods are exposed to Python.

14.2 Glosar

Here are some definition of the most common objects treated in this chapter.

**Parola Master** Password to allow access and decrypt credential stored in the QGIS Authentication DB

**Baza de Date de Autentificare** A Master Password encrypted sqlite db qgis-auth.db where Authentication Configuration are stored. e.g user/password, personal certificates and keys, Certificate Authorities

Authentication DB Authentication Database

Authentication Configuration A set of authentication data depending on Authentication Method. e.g Basic authentication method stores the couple of user/password.

Authentication Config Authentication Configuration

Authentication Method A specific method used to get authenticated. Each method has its own protocol used to gain the authenticated level. Each method is implemented as shared library loaded dynamically during QGIS authentication infrastructure init.

14.3 QgsAuthManager the entry point

The QgsAuthManager singleton is the entry point to use the credentials stored in the QGIS encrypted Authentication DB, i.e. the qgis-auth.db file under the active user profile folder.

This class takes care of the user interaction: by asking to set a master password or by transparently using it to access encrypted stored information.
14.3.1 Init the manager and set the master password

The following snippet gives an example to set master password to open the access to the authentication settings. Code comments are important to understand the snippet.

```python
authMgr = QgsApplication.authManager()

# check if QgsAuthManager has already been initialized... a side effect
# of the QgsAuthManager.init() is that AuthDbPath is set.
# QgsAuthManager.init() is executed during QGIS application init and hence
# you do not normally need to call it directly.
if authMgr.authenticationDatabasePath():
    # already initialised => we are inside a QGIS app.
    if authMgr.masterPasswordIsSet():
        msg = 'Authentication master password not recognized'
        assert authMgr.masterPasswordSame("your master password"), msg
    else:
        msg = 'Master password could not be set'
        # The verify parameter check if the hash of the password was
        # already saved in the authentication db
        assert authMgr.setMasterPassword("your master password",
                                               verify=True), msg
    else:
        # outside qgis, e.g. in a testing environment => setup env var before
        # db init
        os.environ['QGIS_AUTH_DB_DIR_PATH'] = "/path/where/located/qgis-auth.db"
        msg = 'Master password could not be set'
        assert authMgr.setMasterPassword("your master password", True), msg
        authMgr.init("/path/where/located/qgis-auth.db")
```

14.3.2 Populate authdb with a new Authentication Configuration entry

Any stored credential is a Authentication Configuration instance of the QgsAuthMethodConfig class accessed using a unique string like the following one:

```python
authcfg = 'fm1s770'
```

that string is generated automatically when creating an entry using the QGIS API or GUI. but it might be useful to manually set it to a known value in case the configuration must be shared (with different credentials) between multiple users within an organization.

QgsAuthMethodConfig is the base class for any Authentication Method. Any Authentication Method sets a configuration hash map where authentication informations will be stored. Hereafter an useful snippet to store PKI-path credentials for an hypothetic alice user:

```python
authMgr = QgsApplication.authManager()
# set alice PKI data
config = QgsAuthMethodConfig()
config.setName("alice")
config.setMethod("PKI-Paths")
config.setUri("https://example.com")
config.setConfig("certpath", "path/to/alice-cert.pem")
config.setConfig("keypath", "path/to/alice-key.pem")
# check if method parameters are correctly set
assert config.isValid()
# register alice data in authdb returning the `authcfg` of the stored
# configuration
authMgr.storeAuthenticationConfig(config)
newAuthCfgId = config.id()
assert newAuthCfgId
```

14.3. QgsAuthManager the entry point
Available Authentication methods

Authentication Method libraries are loaded dynamically during authentication manager init. Available authentication methods are:

1. Basic User and password authentication
2. Esri-Token ESRI token based authentication
3. Identity-Cert Identity certificate authentication
4. OAuth2 OAuth2 authentication
5. PKI-Paths PKI paths authentication
6. Autentificare PKI-PKCS#12 PKI PKCS#12

Populate Authorities

```python
authMgr = QgsApplication.authManager()
# add authorities
cacerts = QSslCertificate.fromPath( "/path/to/ca_chains.pem" )
assert cacerts is not None
# store CA
authMgr.storeCertAuthorities(cacerts)
# and rebuild CA caches
authMgr.rebuildCaCertsCache()
authMgr.rebuildTrustedCaCertsCache()
```

Manage PKI bundles with QgsPkiBundle

A convenience class to pack PKI bundles composed on SslCert, SslKey and CA chain is the QgsPkiBundle class. Hereafter a snippet to get password protected:

```python
# add alice cert in case of key with pwd
cabundlesList = [] # List of CA bundles
bundle = QgsPkiBundle.fromPemPaths( "/path/to/alice-cert.pem", "/path/to/alice-key_w-pass.pem", 
"unlock_pwd", 
caBundlesList )
assert bundle is not None
# You can check bundle validity by calling:
# bundle.isValid()
```

Refer to QgsPkiBundle class documentation to extract cert/key/CAs from the bundle.

14.3.3 Remove an entry from authdb

We can remove an entry from Authentication Database using it’s authcfg identifier with the following snippet:

```python
authMgr = QgsApplication.authManager()
authMgr.removeAuthenticationConfig( "authCfg_Id_to_remove" )
```
14.3.4 Leave authcfg expansion to QgsAuthManager

The best way to use an Authentication Config stored in the Authentication DB is referring it with the unique identifier authcfg. Expanding, means convert it from an identifier to a complete set of credentials. The best practice to use stored Authentication Configs, is to leave it managed automatically by the Authentication manager. The common use of a stored configuration is to connect to an authentication enabled service like a WMS or WFS or to a DB connection.

Nota: Take into account that not all QGIS data providers are integrated with the Authentication infrastructure. Each authentication method, derived from the base class QgsAuthMethod and support a different set of Providers. For example the certIdentity() method supports the following list of providers:

```python
authM = QgsApplication.authManager()
p = print(authM.authMethod("Identity-Cert").supportedDataProviders())
```

Sample output:

```
['ows', 'wfs', 'wcs', 'wms', 'postgres']
```

For example, to access a WMS service using stored credentials identified with authcfg = 'fm1s770', we just have to use the authcfg in the data source URL like in the following snippet:

```python
authCfg = 'fm1s770'
quiri = QgsDataSourceUri()
quiri.setParam("layers", 'usa:states')
quiri.setParam("styles", '')
quiri.setParam("format", 'image/png')
quiri.setParam("crs", 'EPSG:4326')
quiri.setParam("dpiMode", '7')
quiri.setParam("featureCount", '10')
quiri.setParam("authcfg", authCfg) # ---- here my authCfg url parameter
quiri.setParam("contextualWMSLegend", '0')
quiri.setParam("url", 'https://my_auth_enabled_server_ip/wms')
rlayer = QgsRasterLayer(str(quiri.encodedUri(), "utf-8"), 'states', 'wms')
```

In the upper case, the wms provider will take care to expand authcfg URI parameter with credential just before setting the HTTP connection.

Atentionare: The developer would have to leave authcfg expansion to the QgsAuthManager, in this way he will be sure that expansion is not done too early.

Usually an URI string, built using the QgsDataSourceURI class, is used to set a data source in the following way:

```python
authCfg = 'fm1s770'
quiri = QgsDataSourceUri("my WMS uri here")
quiri.setParam("authcfg", authCfg)
rlayer = QgsRasterLayer( quiri.uri(False), 'states', 'wms')
```

Nota: The False parameter is important to avoid URI complete expansion of the authcfg id present in the URI.
PKI examples with other data providers

Other example can be read directly in the QGIS tests upstream as in test_authmanager_pki_ows or test_authmanager_pki_postgres.

14.4 Adapt plugins to use Authentication infrastructure

Many third party plugins are using httplib2 or other Python networking libraries to manage HTTP connections instead of integrating with QgsNetworkAccessManager and its related Authentication Infrastructure integration.

To facilitate this integration a helper Python function has been created called NetworkAccessManager. Its code can be found here.

This helper class can be used as in the following snippet:

```python
http = NetworkAccessManager(authid="my_authCfg", exception_class=My_
    →FailedRequestError)
try:
    response, content = http.request( "my_rest_url" )
except My_FailedRequestError, e:
    # Handle exception
    pass
```

14.5 Authentication GUIs

In this paragraph are listed the available GUIs useful to integrate authentication infrastructure in custom interfaces.

14.5.1 GUI to select credentials

If it’s necessary to select an Authentication Configuration from the set stored in the Authentication DB it is available in the GUI class QgsAuthConfigSelect.

![Authentication GUI](attachment:image.png)

and can be used as in the following snippet:

```python
# create the instance of the QgsAuthConfigSelect GUI hierarchically linked to
# the widget referred with ‘parent’
parent = QWidget()  # Your GUI parent widget
gui = QgsAuthConfigSelect( parent, "postgres" )
# add the above created gui in a new tab of the interface where the
# GUI has to be integrated
tabGui = QTabWidget()
tabGui.addTab( 1, gui, "Configurations" )
```
The above example is taken from the QGIS source code. The second parameter of the GUI constructor refers to data provider type. The parameter is used to restrict the compatible Authentication Methods with the specified provider.

### 14.5.2 Authentication Editor GUI

The complete GUI used to manage credentials, authorities and to access to Authentication utilities is managed by the `QgsAuthEditorWidgets` class.

![Authentication Editor GUI](image)

and can be used as in the following snippet:

```python
# create the instance of the QgsAuthEditorWidgets GUI hierarchically linked to
# the widget referred with 'parent'
parent = QWidget()  # Your GUI parent widget
ui = QgsAuthEditorWidgets( parent )
ui.show()
```

An integrated example can be found in the related test.

### 14.5.3 Authorities Editor GUI

A GUI used to manage only authorities is managed by the `QgsAuthAuthoritiesEditor` class.

and can be used as in the following snippet:

```python
# create the instance of the QgsAuthAuthoritiesEditor GUI hierarchically
# linked to the widget referred with 'parent'
parent = QWidget()  # Your GUI parent widget
ui = QgsAuthAuthoritiesEditor( parent )
ui.show()
```
Capitolul 14. Infrastructura de autentificare

```python
In [12]: a = QgsAuth AuthoritiesEditor()
In [13]: a.show()
```
The code snippets on this page need the following imports if you’re outside the pyqgis console:

```python
from qgis.core import 
QgsProcessingContext, 
QgsTaskManager, 
QgsTask, 
QgsProcessingAlgRunnerTask, 
Qgis, 
QgsProcessingFeedback, 
QgsApplication, 
QgsMessageLog,
```

14.5. Authentication GUIs  93
15.1 Introducere

Background processing using threads is a way to maintain a responsive user interface when heavy processing is going on. Tasks can be used to achieve threading in QGIS.

A task (QgsTask) is a container for the code to be performed in the background, and the task manager (QgsTaskManager) is used to control the running of the tasks. These classes simplify background processing in QGIS by providing mechanisms for signaling, progress reporting and access to the status for background processes. Tasks can be grouped using subtasks.

The global task manager (found with QgsApplication.taskManager()) is normally used. This means that your tasks may not be the only tasks that are controlled by the task manager.

There are several ways to create a QGIS task:

- Create your own task by extending QgsTask

```python
class SpecialisedTask(QgsTask):
    pass
```

- Create a task from a function

```python
def heavyFunction():
    # Some CPU intensive processing ...
    pass

def workdone():
    # ... do something useful with the results
    pass

task = QgsTask.fromFunction('heavy function', heavyFunction, onfinished=workdone)
```

- Create a task from a processing algorithm

```python
params = dict()
context = QgsProcessingContext()
feedback = QgsProcessingFeedback()
```

(continues on next page)
Dependencies between tasks can be described using the `addSubTask` function of `QgsTask`. When a dependency is stated, the task manager will automatically determine how these dependencies will be executed. Wherever possible dependencies will be executed in parallel in order to satisfy them as quickly as possible. If a task on which another task depends is canceled, the dependent task will also be canceled. Circular dependencies can make deadlocks possible, so be careful.

If a task depends on a layer being available, this can be stated using the `setDependentLayers` function of `QgsTask`. If a layer on which a task depends is not available, the task will be canceled.

Once the task has been created it can be scheduled for running using the `addTask` function of the task manager. Adding a task to the manager automatically transfers ownership of that task to the manager, and the manager will cleanup and delete tasks after they have executed. The scheduling of the tasks is influenced by the task priority, which is set in `addTask`.

The status of tasks can be monitored using `QgsTask` and `QgsTaskManager` signals and functions.

### 15.2 Exemple

#### 15.2.1 Extending QgsTask

In this example `RandomIntegerSumTask` extends `QgsTask` and will generate 100 random integers between 0 and 500 during a specified period of time. If the random number is 42, the task is aborted and an exception is raised. Several instances of `RandomIntegerSumTask` (with subtasks) are generated and added to the task manager, demonstrating two types of dependencies.
```python
def run(self):
    """Here you implement your heavy lifting.
    Should periodically test for isCanceled() to gracefully
    abort.
    This method MUST return True or False.
    Raising exceptions will crash QGIS, so we handle them
    internally and raise them in self.finished
    ""
    QgsMessageLog.logMessage('Started task "/"'.format(
        self.description()),
        MESSAGE_CATEGORY, Qgis.Info)
    wait_time = self.duration / 100
    for i in range(100):
        sleep(wait_time)
        # use setProgress to report progress
        self.setProgress(i)
        arandominteger = random.randint(0, 500)
        self.total += arandominteger
        self.iterations += 1
        # check isCanceled() to handle cancellation
        if self.isCanceled():
            return False
        # simulate exceptions to show how to abort task
        if arandominteger == 42:
            # DO NOT raise Exception('bad value!')
            # this would crash QGIS
            self.exception = Exception('bad value!')
            return False
    return True

def finished(self, result):
    """
    This function is automatically called when the task has
    completed (successfully or not).
    You implement finished() to do whatever follow-up stuff
    should happen after the task is complete.
    finished is always called from the main thread, so it's safe
    to do GUI operations and raise Python exceptions here.
    result is the return value from self.run.
    ""
    if result:
        QgsMessageLog.logMessage(
            'RandomTask "%(name)s" completed\n' \n            'RandomTotal: %(total) (with %(iterations) ' \n            'iterations)'.format(
                name=self.description(),
                total=self.total,
                iterations=self.iterations),
                MESSAGE_CATEGORY, Qgis.Success)
    else:
        if self.exception is None:
            QgsMessageLog.logMessage(
                'RandomTask "%(name)s" not successful but without '
                'exception (probably the task was manually ' \n                'canceled by the user)'.format(
                    name=self.description()),
                    MESSAGE_CATEGORY, Qgis.Warning)
        else:
            QgsMessageLog.logMessage(
                'RandomTask "%(name)s" Exception: %(exception)' .format(
                    name=self.description()),
```

(continues on next page)
exception = self.exception,
MESSAGECATEGORY, Qgs.Critical)
raise self.exception

def cancel(self):
    QgsMessageLog.logMessage(
        'RandomTask "{}" was canceled'.format({
            name=self.description(),
        },
MESSAGECATEGORY, Qgs.Info)
    super().cancel()

longtask = RandomIntegerSumTask('waste cpu long', 20)
shorttask = RandomIntegerSumTask('waste cpu short', 10)
mintask = RandomIntegerSumTask('waste cpu mini', 5)
shortsubtask = RandomIntegerSumTask('waste cpu subtask short', 5)
longsubtask = RandomIntegerSumTask('waste cpu subtask long', 10)
shortestsubtask = RandomIntegerSumTask('waste cpu subtask shortest', 4)

# Add a subtask (shortsubtask) to shorttask that must run after
# mintask and longtask has finished
shorttask.addSubTask(shortsubtask, [mintask, longtask])
# Add a subtask (longsubtask) to longtask that must be run
# before the parent task
longtask.addSubTask(longsubtask, [], QgsTask.ParentDependsOnSubTask)
# Add a subtask (shortestsubtask) to longtask
longtask.addSubTask(shortestsubtask)
QgsApplication.taskManager().addTask(longtask)
QgsApplication.taskManager().addTask(shorttask)
QgsApplication.taskManager().addTask(mintask)

RandomIntegerSumTask(0): Started task "waste cpu subtask shortest"
RandomIntegerSumTask(0): Started task "waste cpu short"
RandomIntegerSumTask(0): Started task "waste cpu mini"
RandomIntegerSumTask(0): Started task "waste cpu subtask long"
RandomIntegerSumTask(3): Task "waste cpu subtask shortest" completed
RandomTotal: 25452 (with 100 iterations)
RandomIntegerSumTask(3): Task "waste cpu mini" completed
RandomTotal: 23810 (with 100 iterations)
RandomIntegerSumTask(3): Task "waste cpu subtask long" completed
RandomTotal: 26308 (with 100 iterations)
RandomIntegerSumTask(3): Task "waste cpu long" completed
RandomTotal: 22534 (with 100 iterations)

15.2.2 Task from function

Create a task from a function (doSomething in this example). The first parameter of the function will hold the
QgsTask for the function. An important (named) parameter is on_finished, that specifies a function that will
be called when the task has completed. The doSomething function in this example has an additional named
parameter wait_time.

import random
from time import sleep
MESSAGECATEGORY = 'TaskFromFunction'

def doSomething(task, wait_time):

(continues on next page)
"""
Raises an exception to abort the task.
Returns a result if success.
The result will be passed, together with the exception (None in
the case of success), to the onFinished method.
If there is an exception, there will be no result.
"""
QgsMessageLog.logMessage('Started task {0}'.format(task.description()),
MESSAGE_CATEGORY, Qgis.Info)
wait_time = wait_time / 100
total = 0
iterations = 0
for i in range(100):
    sleep(wait_time)
    # use task.setProgress to report progress
    task.setProgress(i)
    arandominteger = random.randint(0, 500)
    total += arandominteger
    iterations += 1
    # check task.isCanceled() to handle cancellation
    if task.isCanceled():
        stopped(task)
        return None
    # raise an exception to abort the task
    if arandominteger == 42:
        raise Exception('bad value!')
return {'total': total, 'iterations': iterations,
    'task': task.description()}
def stopped(task):
    QgsMessageLog.logMessage(  
        'Task "{0}" was canceled'.format(
            name=task.description()),
        MESSAGE_CATEGORY, Qgis.Info)

def completed(exception, result=None):
    """This is called when doSomething is finished.
Exception is not None if doSomething raises an exception.
result is the return value of doSomething."""
if exception is None:
    if result is None:
        QgsMessageLog.logMessage(
            'Completed with no exception and no result \'
            '(probably manually canceled by the user)',
            MESSAGE_CATEGORY, Qgis.Warning)
    else:
        QgsMessageLog.logMessage(  
            'Task {0} completed
'  
            'Total: {1} (with {2} iterations)'
            'iterations)',
            name=result['task'],
            total=result['total'],
            iterations=result['iterations']),
        MESSAGECATEGORY, Qgis.Info)
else:
    QgsMessageLog.logMessage("Exception: {0}".format(exception),,
        MESSAGECATEGORY, Qgis.Critical)
    raise exception

# Create a few tasks
task1 = QgsTask.fromFunction('Waste cpu 1', doSomething,
15.2.3 Task from a processing algorithm

Create a task that uses the algorithm qgis:randompointsinextent to generate 50000 random points inside a specified extent. The result is added to the project in a safe way.

```python
from functools import partial
from qgis.core import (QgsTaskManager, QgsMessageLog,
                        QgsProcessingAlgRunnerTask, QgsApplication,
                        QgsProcessingContext, QgsProcessingFeedback,
                        QgsProject)

MESSAGE_CATEGORY = 'AlgRunnerTask'

def task_finished(context, successful, results):
    if not successful:
        QgsMessageLog.logMessage('Task finished unsuccessfully',
                                  MESSAGE_CATEGORY, Qgis.Warning)
        output_layer = context.getMapLayer(results['OUTPUT'])
    # because getMapLayer doesn't transfer ownership, the layer will
    # be deleted when context goes out of scope and you'll get a
    # crash.
    # takeMapLayer transfers ownership so it's then safe to add it
    # to the project and give the project ownership.
    if output_layer and output_layer.isValid():
        QgsProject.instance().addMapLayer(
            context.takeResultLayer(output_layer.id()))

alg = QgsApplication.processingRegistry().algorithmById(
    'qgis:randompointsinextent')
context = QgsProcessingContext()
feedback = QgsProcessingFeedback()
params = {
    'EXTENT': '0.0,10.0,40,50 [EPSG:4326]',
    'MIN_DISTANCE': 0.0,
    'POINTS_NUMBER': 50000,
    'TARGET_CRS': 'EPSG:4326',
    'OUTPUT': 'memory:My random points'
}
task = QgsProcessingAlgRunnerTask(alg, params, context, feedback)
task.executed.connect(partial(task_finished, context))
QgsApplication.taskManager().addTask(task)
```

100 Capitolul 15. Tasks - doing heavy work in the background
16.1 Structuring Python Plugins

- Writing a plugin
  - Filele Plugin-ului
- Plugin content
  - Plugin metadata
  - __init__.py
  - mainPlugin.py
  - Resource File
- Documentation
- Translation
  - Software requirements
  - Files and directory
    * .pro file
    * .ts file
    * .qm file
  - Translate using Makefile
  - Load the plugin
- Tips and Tricks
  - Plugin Reloader
  - Accessing Plugins
  - Log Messages
  - Share your plugin
In order to create a plugin, here are some steps to follow:

1. **Idea**: Have an idea about what you want to do with your new QGIS plugin. Why do you do it? What problem do you want to solve? Is there already another plugin for that problem?

2. **Create files**: some are essentials (see *Fișierele Plugin-ului*).

3. **Write code**: Write the code in appropriate files.

4. **Test**: Reload your plugin to check if everything is OK.

5. **Publish**: Publish your plugin in QGIS repository or make your own repository as an „arsenal” of personal „GIS weapons”.

### 16.1.1 Writing a plugin

Since the introduction of Python plugins in QGIS, a number of plugins have appeared. The QGIS team maintains an *Official Python plugin repository*. You can use their source to learn more about programming with PyQGIS or find out whether you are duplicating development effort.

#### Fișierele Plugin-ului

Here’s the directory structure of our example plugin:

```bash
PYTHON_PLUGINS_PATH/
MyPlugin/
  __init__.py  --> *required*
  mainPlugin.py --> *core code*
  metadata.txt  --> *required*
  resources.qrc --> *likely useful*
  resources.py --> *compiled version, likely useful*
  form.ui  --> *likely useful*
  form.py --> *compiled version, likely useful*
```

What is the meaning of the files:

- **__init__.py** = The starting point of the plugin. It has to have the `classFactory()` method and may have any other initialisation code.
- **mainPlugin.py** = The main working code of the plugin. Contains all the information about the actions of the plugin and the main code.
- **resources.qrc** = The .xml document created by Qt Designer. Contains relative paths to resources of the forms.
- **resources.py** = The translation of the .qrc file described above to Python.
- **form.ui** = The GUI created by Qt Designer.
- **form.py** = The translation of the form.ui described above to Python.
- **metadata.txt** = Contains general info, version, name and some other metadata used by plugins website and plugin infrastructure.

Here is a way of creating the basic files (skeleton) of a typical QGIS Python plugin.

There is a QGIS plugin called *Plugin Builder 3* that creates a plugin template for QGIS. This is the recommended option, as it produces 3.x compatible sources.

**Atentionare**: If you plan to upload the plugin to the *Official Python plugin repository* you must check that your plugin follows some additional rules, required for plugin validation.
16.1.2 Plugin content

Here you can find information and examples about what to add in each of the files in the file structure described above.

Plugin metadata

First, the plugin manager needs to retrieve some basic information about the plugin such as its name, description etc. File `metadata.txt` is the right place to put this information.

**Nota:** All metadata must be in UTF-8 encoding.

<table>
<thead>
<tr>
<th>Metadata name</th>
<th>Required</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>True</td>
<td>a short string containing the name of the plugin</td>
</tr>
<tr>
<td>qgisMinimumVersion</td>
<td>True</td>
<td>dotted notation of minimum QGIS version</td>
</tr>
<tr>
<td>qgisMaximumVersion</td>
<td>False</td>
<td>dotted notation of maximum QGIS version</td>
</tr>
<tr>
<td>descriere</td>
<td>True</td>
<td>short text which describes the plugin, no HTML allowed</td>
</tr>
<tr>
<td>about</td>
<td>True</td>
<td>longer text which describes the plugin in details, no HTML allowed</td>
</tr>
<tr>
<td>version</td>
<td>True</td>
<td>short string with the version dotted notation</td>
</tr>
<tr>
<td>author</td>
<td>True</td>
<td>author name</td>
</tr>
<tr>
<td>email</td>
<td>True</td>
<td>email of the author, only shown on the website to logged in users, but visible in the Plugin Manager after the plugin is installed</td>
</tr>
<tr>
<td>changelog</td>
<td>False</td>
<td>string, can be multiline, no HTML allowed</td>
</tr>
<tr>
<td>experimental</td>
<td>False</td>
<td>boolean flag, <code>True or False</code> - True if this version is experimental</td>
</tr>
<tr>
<td>deprecated</td>
<td>False</td>
<td>boolean flag, <code>True or False</code>, applies to the whole plugin and not just to the uploaded version</td>
</tr>
<tr>
<td>etichete</td>
<td>False</td>
<td>comma separated list, spaces are allowed inside individual tags</td>
</tr>
<tr>
<td>homepage</td>
<td>False</td>
<td>a valid URL pointing to the homepage of your plugin</td>
</tr>
<tr>
<td>repository</td>
<td>True</td>
<td>a valid URL for the source code repository</td>
</tr>
<tr>
<td>tracker</td>
<td>False</td>
<td>a valid URL for tickets and bug reports</td>
</tr>
<tr>
<td>icon</td>
<td>False</td>
<td>a file name or a relative path (relative to the base folder of the plugin's compressed package) of a web friendly image (PNG, JPEG)</td>
</tr>
<tr>
<td>category</td>
<td>False</td>
<td>one of Raster, Vector, Database and Web</td>
</tr>
<tr>
<td>plugin_dependencies</td>
<td>False</td>
<td>PIP-like comma separated list of other plugins to install</td>
</tr>
<tr>
<td>server</td>
<td>False</td>
<td>boolean flag, <code>True or False</code>, determines if the plugin has a server interface</td>
</tr>
<tr>
<td>hasProcessingProvider</td>
<td>False</td>
<td>boolean flag, <code>True or False</code>, determines if the plugin provides processing algorithms</td>
</tr>
</tbody>
</table>

By default, plugins are placed in the **Plugins** menu (we will see in the next section how to add a menu entry for your plugin) but they can also be placed into **Raster**, **Vector**, **Database** and **Web** menus.

A corresponding „category” metadata entry exists to specify that, so the plugin can be classified accordingly. This metadata entry is used as tip for users and tells them where (in which menu) the plugin can be found. Allowed values for „category” are: Vector, Raster, Database or Web. For example, if your plugin will be available from **Raster** menu, add this to `metadata.txt`

```plaintext
category=Raster
```

**Nota:** If `qgisMaximumVersion` is empty, it will be automatically set to the major version plus .99 when uploaded to the **Official Python plugin repository.**
An example for this metadata.txt

```plaintext
; the next section is mandatory
[general]
name=HelloWorld
email=me@example.com
author=Just Me
gqisMinimumVersion=3.0
description=This is an example plugin for greeting the world.
    Multiline is allowed:
        lines starting with spaces belong to the same
        field, in this case to the "description" field.
    HTML formatting is not allowed.
about=This paragraph can contain a detailed description
    of the plugin. Multiline is allowed, HTML is not.
version=version 1.2
tracker=http://bugs.itopen.it
repository=http://www.itopen.it/repo
; end of mandatory metadata

; start of optional metadata
category=Raster
changelog=The changelog lists the plugin versions
    and their changes as in the example below:
        1.0 - First stable release
        0.9 - All features implemented
        0.8 - First testing release

tags=wkt,raster,hello world

; these metadata can be empty, they will eventually become mandatory.
homepage=https://www.itopen.it
icon=icon.png

; experimental flag (applies to the single version)
experimental=True

; deprecated flag (applies to the whole plugin and not only to the uploaded
    version)
deprecated=False

; if empty, it will be automatically set to major version + .99
gqisMaximumVersion=3.99

; Since QGIS 3.8, a comma separated list of plugins to be installed
; (or upgraded) can be specified.
; The example below will try to install (or upgrade) "MyOtherPlugin" version 1.12
; and any version of "YetAnotherPlugin"
plugin_dependencies=MyOtherPlugin==1.12,YetAnotherPlugin
```
This is the required by Python's import system. Also, QGIS requires that this file contains a `classFactory()` function, which is called when the plugin gets loaded into QGIS. It receives a reference to the instance of `QgisInterface` and must return an object of your plugin's class from the `mainplugin.py` — in our case it's called `TestPlugin` (see below). This is how `__init__.py` should look like:

```python
def classFactory(iface):
    from .mainPlugin import TestPlugin
    return TestPlugin(iface)
# any other initialisation needed
```

This is where the magic happens and this is how magic looks like: (e.g. `mainPlugin.py`)

```python
from qgis.PyQt.QtGui import *
from qgis.PyQt.QtWidgets import *
# initialize Qt resources from file resources.py
from . import resources

class TestPlugin:
    def __init__(self, iface):
        # save reference to the QGIS interface
        self iface = iface

    def initGui(self):
        # create action that will start plugin configuration
        self action = QAction(QIcon(":/plugins/testplug/icon.png"),
                                "Test plugin",
                                self iface.mainWindow())
        self.action.setObjectName("testAction")
        self.action.setWhatsThis("Configuration for test plugin")
        self.action.setStatusTip("This is status tip")
        self.action.triggered.connect(self.run)

        # add toolbar button and menu item
        self iface.addToolBarIcon(self.action)
        self iface.addPluginToMenu("&Test plugins", self.action)

        # connect to signal renderComplete which is emitted when canvas
        # rendering is done
        self iface.mapCanvas().renderComplete.connect(self.renderTest)

    def unload(self):
        # remove the plugin menu item and icon
        self iface.removePluginMenu("&Test plugins", self.action)
        self iface.removeToolBarIcon(self.action)

        # disconnect from signal of the canvas
        self iface.mapCanvas().renderComplete.disconnect(self.renderTest)

    def run(self):
        # create and show a configuration dialog or something similar
        print("TestPlugin: run called!")

    def renderTest(self, self, painter):
```

(continues on next page)
The only plugin functions that must exist in the main plugin source file (e.g. `mainPlugin.py`) are:

- `__init__` which gives access to QGIS interface
- `initGui()` called when the plugin is loaded
- `unload()` called when the plugin is unloaded

In the above example, `addPluginToMenu` is used. This will add the corresponding menu action to the `Plugins` menu. Alternative methods exist to add the action to a different menu. Here is a list of those methods:

- `addPluginToRasterMenu()`
- `addPluginToVectorMenu()`
- `addPluginToDatabaseMenu()`
- `addPluginToWebMenu()`

All of them have the same syntax as the `addPluginToMenu` method.

Adding your plugin menu to one of those predefined method is recommended to keep consistency in how plugin entries are organized. However, you can add your custom menu group directly to the menu bar, as the next example demonstrates:

```python
def initGui(self):
    self.menu = QMenu(self.iface.mainWindow())
    self.menu.setObjectName("testMenu")
    self.menu.setTitle("MyMenu")

    self.action = QAction(QIcon(":/plugins/testplug/icon.png"),
                          "Test plugin",
                          self.iface.mainWindow())
    self.action.setObjectName("testAction")
    self.action.setWhatsThis("Configuration for test plugin")
    self.action.setStatusTip("This is status tip")
    self.action.triggered.connect(self.run)
    self.menu.addAction(self.action)

    menuBar = self.iface.mainWindow().menuBar()
    menuBar.insertMenu(self.iface.firstRightStandardMenu().menuAction(),
                       self.menu)

def unload(self):
    self.menu.deleteLater()
```

Don’t forget to set `QAction` and `QMenu` `objectName` to a name specific to your plugin so that it can be customized.

### Resource File

You can see that in `initGui()` we’ve used an icon from the resource file (called `resources.qrc` in our case)

```xml
<RCC>
    <qresource prefix="/plugins/testplug" >
        <file>icon.png</file>
    </qresource>
</RCC>
```
It is good to use a prefix that will not collide with other plugins or any parts of QGIS, otherwise you might get resources you did not want. Now you just need to generate a Python file that will contain the resources. It’s done with `pyrcc5` command:

```
pyrcc5 -o resources.py resources.qrc
```

**Nota:** In Windows environments, attempting to run the `pyrcc5` from Command Prompt or Powershell will probably result in the error „Windows cannot access the specified device, path, or file […].” The easiest solution is probably to use the OSGeo4W Shell but if you are comfortable modifying the PATH environment variable or specifying the path to the executable explicitly you should be able to find it at `<Your QGIS Install Directory>\bin\pyrcc5.exe`.

And that’s all… nothing complicated :)

If you’ve done everything correctly you should be able to find and load your plugin in the plugin manager and see a message in console when toolbar icon or appropriate menu item is selected.

When working on a real plugin it’s wise to write the plugin in another (working) directory and create a makefile which will generate UI + resource files and install the plugin into your QGIS installation.

### 16.1.3 Documentation

The documentation for the plugin can be written as HTML help files. The `qgis.utils` module provides a function, `showPluginHelp()` which will open the help file browser, in the same way as other QGIS help.

The `showPluginHelp()` function looks for help files in the same directory as the calling module. It will look for, in turn, `index-ll_cc.html`, `index-ll.html`, `index-en.html`, `index-en_us.html` and `index.html`, displaying whichever it finds first. Here `ll_cc` is the QGIS locale. This allows multiple translations of the documentation to be included with the plugin.

The `showPluginHelp()` function can also take parameters `packageName`, which identifies a specific plugin for which the help will be displayed, `filename`, which can replace “index” in the names of files being searched, and `section`, which is the name of an html anchor tag in the document on which the browser will be positioned.

### 16.1.4 Translation

With a few steps you can set up the environment for the plugin localization so that depending on the locale settings of your computer the plugin will be loaded in different languages.

**Software requirements**

The easiest way to create and manage all the translation files is to install Qt Linguist. In a Debian-based GNU/Linux environment you can install it typing:

```
sudo apt install qttools5-dev-tools
```

16.1. Structuring Python Plugins
Files and directory

When you create the plugin you will find the i18n folder within the main plugin directory.

All the translation files have to be within this directory.

.pro file

First you should create a .pro file, that is a project file that can be managed by Qt Linguist.

In this .pro file you have to specify all the files and forms you want to translate. This file is used to set up the localization files and variables. A possible project file, matching the structure of our example plugin:

```
FORMS = ../../../form.ui
SOURCES = ../../../your_plugin.py
TRANSLATIONS = your_plugin_it.ts
```

Your plugin might follow a more complex structure, and it might be distributed across several files. If this is the case, keep in mind that pylupdate5, the program we use to read the .pro file and update the translatable string, does not expand wild card characters, so you need to place every file explicitly in the .pro file. Your project file might then look like something like this:

```
FORMS = ../../../ui/about.ui ../../../ui/feedback.ui 
       ../../../ui/main_dialog.ui
SOURCES = ../../../your_plugin.py ../../../computation.py 
          ../../../utils.py
```

Furthermore, the your_plugin.py file is the file that calls all the menu and sub-menus of your plugin in the QGIS toolbar and you want to translate them all.

Finally with the TRANSLATIONS variable you can specify the translation languages you want.

```
Atenciónare: Be sure to name the ts file like your_plugin_+language+.ts otherwise the language loading will fail! Use the 2 letter shortcut for the language (it for Italian, de for German, etc...)
```

.ts file

Once you have created the .pro you are ready to generate the .ts file(s) for the language(s) of your plugin.

Open a terminal, go to your_plugin/i18n directory and type:

```
pylupdate5 your_plugin.pro
```

you should see the your_plugin_language.ts file(s).

Open the .ts file with Qt Linguist and start to translate.

.qm file

When you finish to translate your plugin (if some strings are not completed the source language for those strings will be used) you have to create the .qm file (the compiled .ts file that will be used by QGIS).

Just open a terminal cd in your_plugin/i18n directory and type:

```
lrelease your_plugin.ts
```

now, in the i18n directory you will see the your_plugin.qm file(s).
## Translate using Makefile

Alternatively you can use the makefile to extract messages from python code and Qt dialogs, if you created your plugin with Plugin Builder. At the beginning of the Makefile there is a LOCALES variable:

```makefile
LOCALES = en
```

Add the abbreviation of the language to this variable, for example for Hungarian language:

```makefile
LOCALES = en hu
```

Now you can generate or update the `hu.ts` file (and the `en.ts` too) from the sources by:

```bash
make transup
```

After this, you have updated `.ts` file for all languages set in the `LOCALES` variable. Use [Qt Linguist](https://doc.qt.io/qt-5/qlinguist.html) to translate the program messages. Finishing the translation the `.qm` files can be created by the transcompile:

```bash
make transcompile
```

You have to distribute `.ts` files with your plugin.

### Load the plugin

In order to see the translation of your plugin, open QGIS, change the language (`Settings → Options → General`) and restart QGIS.

You should see your plugin in the correct language.

---

**Atentionare:** If you change something in your plugin (new UIs, new menu, etc...) you have to **generate again** the update version of both `.ts` and `.qm` file, so run again the command of above.

### 16.1.5 Tips and Tricks

#### Plugin Reloader

During development of your plugin you will frequently need to reload it in QGIS for testing. This is very easy using the `Plugin Reloader` plugin. You can find it with the Plugin Manager.

#### Accessing Plugins

You can access all the classes of installed plugins from within QGIS using python, which can be handy for debugging purposes.

```python
my_plugin = qgis.utils.plugins['My Plugin']
```
Log Messages

Plugins have their own tab within the log_message_panel.

Share your plugin

QGIS is hosting hundreds of plugins in the plugin repository. Consider sharing yours! It will extend the possibilities of QGIS and people will be able to learn from your code. All hosted plugins can be found and installed from within QGIS with the Plugin Manager.

Information and requirements are here: plugins.qgis.org.

16.2 Secvențe De Cod

- Cum se apelează o metodă printr-o comandă rapidă
- Cum se pot comuta straturile
- Cum se accesează tabelul de atribute al funcțiilor selectate
- Interface for plugin in the options dialog

Această secțiune prezintă fragmente de cod destinate dezvoltării de pluginuri.

16.2.1 Cum se apelează o metodă printr-o comandă rapidă

În plugin, adăugăm la initGui():

```python
self.key_action = QAction("Test Plugin", self.iface.mainWindow())
self.iface.registerMainWindowAction(self.key_action, "Ctrl+I")  # action triggered by Ctrl+I
self.iface.addPluginToMenu("&Test plugins", self.key_action)
self.key_action_triggered.connect(self.key_action_triggered)
```

La unload() adăugăm:

```python
self.iface.unregisterMainWindowAction(self.key_action)
```

Metoda care este apelată atunci când se apasă CTRL+I:

```python
def key_action_triggered(self):
    QMessageBox.information(self.iface.mainWindow(), "Ok", "You pressed Ctrl+I")
```

16.2.2 Cum se pot comuta straturile

Există o API dedicat accesării straturilor din legendară. Iată un exemplu care modifică vizibilitatea stratului activ:

```python
root = QgsProject.instance().layerTreeRoot()
node = root.findLayer(iface.activeLayer().id())
new_state = Qt.Checked if node.isVisible() == Qt.Unchecked else Qt.Unchecked
node.setItemVisibilityChecked(new_state)
```
16.2.3 Cum se accesează tabelul de atribute al funcțiilor selectate

```python
def change_value(value):
    # Change the value in the second column for all selected features.

    :param value: The new value.

    layer = iface.activeLayer()
    if layer:
        count_selected = layer.selectedFeatureCount()
        if count_selected > 0:
            layer.startEditing()
            id_features = layer.selectedFeatureIds()
            for i in id_features:
                layer.changeAttributeValue(i, 1, value)  # 1 being the second column
            layer.commitChanges()
        else:
            iface.messageBar().pushCritical("Error", "Please select at least one feature from current layer")
    else:
        iface.messageBar().pushCritical("Error", "Please select a layer")

# The method requires one parameter (the new value for the second
# field of the selected feature(s)) and can be called by
change_value(50)
```

16.2.4 Interface for plugin in the options dialog

You can add a custom plugin options tab to Settings | Options. This is preferable over adding a specific main menu entry for your plugin’s options, as it keeps all of the QGIS application settings and plugin settings in a single place which is easy for users to discover and navigate.

The following snippet will just add a new blank tab for the plugin’s settings, ready for you to populate with all the options and settings specific to your plugin. You can split the following classes into different files. In this example, we are adding two classes into the main mainPlugin.py file.

```python
class MyPluginOptionsFactory(QgsOptionsWidgetFactory):
    def __init__(self):
        super().__init__()

    def icon(self):
        return QIcon('icons/my_plugin_icon.svg')

    def createWidget(self, parent):
        return ConfigOptionsPage(parent)

class ConfigOptionsPage(QgsOptionsPageWidget):
    def __init__(self, parent):
        super().__init__(parent)
        layout = QVBoxLayout()
        layout.setContentsMargins(0, 0, 0, 0)
        self.setLayout(layout)

Finally we are adding the imports and modifying the __init__ function:

```python
from qgis.PyQt.QtWidgets import QVBoxLayout
from qgis.gui import QgsOptionsWidgetFactory, QgsOptionsPageWidget
```
class MyPlugin:
    """QGIS Plugin Implementation."""

    def __init__(self, iface):
        """Constructor.

        :param iface: An interface instance that will be passed to this class
                      which provides the hook by which you can manipulate the QGIS
                      application at run time.
        :type iface: QgsInterface
        """
        # Save reference to the QGIS interface
        self.iface = iface

    def initGui(self):
        self.options_factory = MyPluginOptionsFactory()
        self.options_factory.setTitle(self.tr('My Plugin'))
        iface.registerOptionsWidgetFactory(self.options_factory)

    def unload(self):
        iface.unregisterOptionsWidgetFactory(self.options_factory)

Sfat: You can apply a similar logic to add the plugin custom option to the layer properties dialog using the classes QgsMapLayerConfigWidgetFactory and QgsMapLayerConfigWidget.

16.3 Using Plugin Layers

If your plugin uses its own methods to render a map layer, writing your own layer type based on QgsPluginLayer might be the best way to implement that.

16.3.1 Subclassing QgsPluginLayer

Below is an example of a minimal QgsPluginLayer implementation. It is based on the original code of the Watermark example plugin.

The custom renderer is the part of the implement that defines the actual drawing on the canvas.

class WatermarkLayerRenderer(QgsMapLayerRenderer):

    def __init__(self, layerId, rendererContext):
        super().__init__(layerId, rendererContext)

    def render(self):
        image = QImage("/usr/share/icons/hicolor/128x128/apps/qgis.png")
        painter = self.renderContext().painter()
        painter.save()
        painter.drawImage(10, 10, image)
        painter.restore()
        return True

class WatermarkPluginLayer(QgsPluginLayer):
def __init__(self):
    super().__init__(WatermarkPluginLayer.LAYER_TYPE, "Watermark plugin layer")
    self.setValid(True)

def createMapRenderer(self, rendererContext):
    return WatermarkLayerRenderer(self.id(), rendererContext)

def setTransformContext(self, ct):
    pass

# Methods for reading and writing specific information to the project file can
# also be added:
def readXml(self, node, context):
    pass
def writeXml(self, node, doc, context):
    pass

The plugin layer can be added to the project and to the canvas as any other map layer:

```python
plugin_layer = WatermarkPluginLayer()
QgsProject.instance().addMapLayer(plugin_layer)
```

When loading a project containing such a layer, a factory class is needed:

class WatermarkPluginLayerType(QgsPluginLayerType):
    def __init__(self):
        super().__init__(WatermarkPluginLayer.LAYER_TYPE)

    def createLayer(self):
        return WatermarkPluginLayer()

    # You can also add GUI code for displaying custom information
    # in the layer properties
    def showLayerProperties(self, layer):
        pass

    # Keep a reference to the instance in Python so it won’t
    # be garbage collected
    plt = WatermarkPluginLayerType()

    assert QgsApplication.pluginLayerRegistry().addPluginLayerType(plt)

16.4 IDE settings for writing and debugging plugins

- Useful plugins for writing Python plugins
- A note on configuring your IDE on Linux and Windows
- Debugging using Pyscripter IDE (Windows)
- Debugging using Eclipse and PyDev
Although each programmer has his preferred IDE/Text editor, here are some recommendations for setting up popular IDE’s for writing and debugging QGIS Python plugins.

### 16.4.1 Useful plugins for writing Python plugins

Some plugins are convenient when writing Python plugins. From Plugins ➤ Manage and Install plugins..., install:

- **Plugin reloader**: This will let you reload a plugin and pull new changes without restarting QGIS.
- **First Aid**: This will add a Python console and local debugger to inspect variables when an exception is raised from a plugin.

**Atención**: Despite our constant efforts, information beyond this line may not be updated for QGIS 3. Refer to https://qgis.org/pyqgis/master for the python API documentation or, give a hand to update the chapters you know about. Thanks.

### 16.4.2 A note on configuring your IDE on Linux and Windows

**On Linux**, all that usually needs to be done is to add the QGIS library locations to the user’s PYTHONPATH environment variable. Under most distributions, this can be done by editing ~/.bashrc or ~/.bash-profile with the following line (tested on OpenSUSE Tumbleweed):

```bash
export PYTHONPATH="$PYTHONPATH:/usr/share/qgis/python/plugins:/usr/share/qgis/←python"
```

Save the file and implement the environment settings by using the following shell command:

```bash
source ~/.bashrc
```

**On Windows**, you need to make sure that you have the same environment settings and use the same libraries and interpreter as QGIS. The fastest way to do this is to modify the startup batch file of QGIS. If you used the OSGeo4W Installer, you can find this under the bin folder of your OSGeo4W install. Look for something like C:\OSGeo4W\bin\qgis-unstable.bat.

### 16.4.3 Debugging using Pyscripter IDE (Windows)

For using Pyscripter IDE, here’s what you have to do:

1. Make a copy of qgis-unstable.bat and rename it pyscripter.bat.
2. Open it in an editor. And remove the last line, the one that starts QGIS.
3. Add a line that points to your Pyscripter executable and add the command line argument that sets the version of Python to be used.
4. Also add the argument that points to the folder where Pyscripter can find the Python dll used by QGIS, you can find this under the bin folder of your OSGeoW install.
5. Now when you double click this batch file it will start Pyscripter, with the correct path.

More popular than Pyscripter, Eclipse is a common choice among developers. In the following section, we will be explaining how to configure it for developing and testing plugins.

### 16.4.4 Debugging using Eclipse and PyDev

#### Instalarea

To use Eclipse, make sure you have installed the following:

- Eclipse
- Aptana Studio 3 Plugin or PyDev
- QGIS 2.x

You may also want to install Remote Debug, a QGIS plugin. At the moment it's still experimental so enable Experimental plugins under Plugins ➔ Manage and Install plugins... ➔ Options beforehand.

To prepare your environment for using Eclipse in Windows, you should also create a batch file and use it to start Eclipse:

1. Locate the folder where qgis_core.dll resides in. Normally this is C:\OSGeo4W\apps\qgis\bin, but if you compiled your own QGIS application this is in your build folder in output/bin/RelWithDebInfo
2. Locate your eclipse.exe executable.
3. Create the following script and use this to start eclipse when developing QGIS plugins.

```
call "C:\OSGeo4W\bin\o4w_env.bat"
set PATH=%PATH%;C:\path\to\your\qgis_core.dll\parent\folder
C:\path\to\your\eclipse.exe
```

#### Setting up Eclipse

1. In Eclipse, create a new project. You can select General Project and link your real sources later on, so it does not really matter where you place this project.
2. Right-click your new project and choose New ➔ Folder.
3. Click Advanced and choose Link to alternate location (Linked Folder). In case you already have sources you want to debug, choose these. In case you don't, create a folder as it was already explained.

Now in the view Project Explorer, your source tree pops up and you can start working with the code. You already have syntax highlighting and all the other powerful IDE tools available.
Select a wizard

Create a new project resource

Wizards:

- PHP Project
- Rails Project
- Ruby Project
- Web Project
- General
- Project
  - C/C++
  - CVS
  - Java
  - PyDev
  - Ruby
  - Web
  - Other

Fig. 16.1: Eclipse project
Configuring the debugger

To get the debugger working:

1. Switch to the Debug perspective in Eclipse (Window ▶️ Open Perspective ▶️ Other ▶️ Debug).
2. Start the PyDev debug server by choosing PyDev ▶️ Start Debug Server.
3. Eclipse is now waiting for a connection from QGIS to its debug server and when QGIS connects to the debug server it will allow it to control the python scripts. That’s exactly what we installed the Remote Debug plugin for. So start QGIS in case you did not already and click the bug symbol.

Now you can set a breakpoint and as soon as the code hits it, execution will stop and you can inspect the current state of your plugin. (The breakpoint is the green dot in the image below, set one by double clicking in the white space left to the line you want the breakpoint to be set).

![Fig. 16.2: Breakpoint](image)

A very interesting thing you can make use of now is the debug console. Make sure that the execution is currently stopped at a break point, before you proceed.

1. Open the Console view (Window ▶️ Show view). It will show the Debug Server console which is not very interesting. But there is a button Open Console which lets you change to a more interesting PyDev Debug Console.
2. Click the arrow next to the Open Console button and choose PyDev Console. A window opens up to ask you which console you want to start.
3. Choose PyDev Debug Console. In case its greyed out and tells you to Start the debugger and select the valid frame, make sure that you’ve got the remote debugger attached and are currently on a breakpoint.

![Fig. 16.3: PyDev Debug Console](image)

You have now an interactive console which lets you test any commands from within the current context. You can manipulate variables or make API calls or whatever you like.

**Sfat:** A little bit annoying is, that every time you enter a command, the console switches back to the Debug Server. To stop this behavior, you can click the Pin Console button when on the Debug Server page and it should remember this decision at least for the current debug session.
Making eclipse understand the API

A very handy feature is to have Eclipse actually know about the QGIS API. This enables it to check your code for typos. But not only this, it also enables Eclipse to help you with autocompletion from the imports to API calls.

To do this, Eclipse parses the QGIS library files and gets all the information out there. The only thing you have to do is to tell Eclipse where to find the libraries.

1. Click Window ▶ Preferences ▶ PyDev ▶ Interpreter ▶ Python.

You will see your configured python interpreter in the upper part of the window (at the moment python2.7 for QGIS) and some tabs in the lower part. The interesting tabs for us are Libraries and Forced Builtins.

2. First open the Libraries tab.

3. Add a New Folder and choose the python folder of your QGIS installation. If you do not know where this folder is (it's not the plugins folder):
   1. Open QGIS
   2. Start a python console
   3. Enter `qgis`
   4. and press Enter. It will show you which QGIS module it uses and its path.
   5. Strip the trailing `/qgis/__init__.pyc` from this path and you’ve got the path you are looking for.

4. You should also add your plugins folder here (it is in `python/plugins` under the user profile folder).

5. Next jump to the Forced Builtins tab, click on New... and enter qgis. This will make Eclipse parse the QGIS API. You probably also want Eclipse to know about the PyQt API. Therefore also add PyQt as forced builtin. That should probably already be present in your libraries tab.
6. Click OK and you’re done.

Nota: Every time the QGIS API changes (e.g. if you’re compiling QGIS master and the SIP file changed), you should go back to this page and simply click Apply. This will let Eclipse parse all the libraries again.

16.4.5 Debugging with PyCharm on Ubuntu with a compiled QGIS

PyCharm is an IDE for Python developed by JetBrains. There is a free version called Community Edition and a paid one called Professional. You can download PyCharm on the website: https://www.jetbrains.com/pycharm/download

We are assuming that you have compiled QGIS on Ubuntu with the given build directory ~/dev/qgis/build/master. It’s not compulsory to have a self compiled QGIS, but only this has been tested. Paths must be adapted.

1. In PyCharm, in your Project Properties, Project Interpreter, we are going to create a Python Virtual environment called QGIS.
2. Click the small gear and then Add.
3. Select Virtualenv environment.
4. Select a generic location for all your Python projects such as ~/dev/qgis/venv because we will use this Python interpreter for all our plugins.
5. Choose a Python 3 base interpreter available on your system and check the next two options Inherit global site-packages and Make available to all projects.

1. Click OK, come back on the small gear and click Show all.
2. In the new window, select your new interpreter QGIS and click the last icon in the vertical menu Show paths for the selected interpreter.
3. Finally, add the following absolute path to the list ~/dev/qgis/build/master/output/python.

1. Restart PyCharm and you can start using this new Python virtual environment for all your plugins.

PyCharm will be aware of the QGIS API and also of the PyQt API if you use Qt provided by QGIS like from qgis.PyQt.QtCore import QDir. The autocompletion should work and PyCharm can inspect your code.

In the professional version of PyCharm, remote debugging is working well. For the Community edition, remote debugging is not available. You can only have access to a local debugger, meaning that the code must run inside PyCharm (as script or unittest), not in QGIS itself. For Python code running in QGIS, you might use the First Aid plugin mentioned above.
Capitolul 16. Developing Python Plugins
16.4.6 Debugging using PDB

If you do not use an IDE such as Eclipse or PyCharm, you can debug using PDB, following these steps.

1. First add this code in the spot where you would like to debug

```python
# Use pdb for debugging
import pdb
# also import pyqtRemoveInputHook
from qgis.PyQt.QtCore import pyqtRemoveInputHook
# These lines allow you to set a breakpoint in the app
pyqtRemoveInputHook()
pdb.set_trace()
```

2. Then run QGIS from the command line.
   
   On Linux do:
   ```
   $ ./Qgis
   ```
   
   On macOS do:
   ```
   $ /Applications/Qgis.app/Contents/MacOS/Qgis
   ```

3. And when the application hits your breakpoint you can type in the console!

DE EFECTUAT: Add testing information

16.5 Releasing your plugin

- Metadata and names
- Code and help
- Official Python plugin repository
  - Permissions
  - Trust management
  - Validation
  - Plugin structure

Once your plugin is ready and you think the plugin could be helpful for some people, do not hesitate to upload it to Official Python plugin repository. On that page you can also find packaging guidelines about how to prepare the plugin to work well with the plugin installer. Or in case you would like to set up your own plugin repository, create a simple XML file that will list the plugins and their metadata.

Please take special care to the following suggestions:
16.5.1 Metadata and names

- avoid using a name too similar to existing plugins
- if your plugin has a similar functionality to an existing plugin, please explain the differences in the About field, so the user will know which one to use without the need to install and test it
- avoid repeating „plugin” in the name of the plugin itself
- use the description field in metadata for a 1 line description, the About field for more detailed instructions
- include a code repository, a bug tracker, and a home page; this will greatly enhance the possibility of collaboration, and can be done very easily with one of the available web infrastructures (GitHub, GitLab, Bitbucket, etc.)
- choose tags with care: avoid the uninformative ones (e.g. vector) and prefer the ones already used by others (see the plugin website)
- add a proper icon, do not leave the default one; see QGIS interface for a suggestion of the style to be used

16.5.2 Code and help

- do not include generated file (ui_* .py, resources_rc .py, generated help files...) and useless stuff (e.g. .gitignore) in repository
- add the plugin to the appropriate menu (Vector, Raster, Web, Database)
- when appropriate (plugins performing analyses), consider adding the plugin as a subplugin of Processing framework: this will allow users to run it in batch, to integrate it in more complex workflows, and will free you from the burden of designing an interface
- include at least minimal documentation and, if useful for testing and understanding, sample data.

16.5.3 Official Python plugin repository

You can find the official Python plugin repository at https://plugins.qgis.org/.
In order to use the official repository you must obtain an OSGEO ID from the OSGEO web portal.
Once you have uploaded your plugin it will be approved by a staff member and you will be notified.
DE EFECTUAT: Insert a link to the governance document

Permissions

These rules have been implemented in the official plugin repository:

- every registered user can add a new plugin
- staff users can approve or disapprove all plugin versions
- users which have the special permission plugins.can_approve get the versions they upload automatically approved
- users which have the special permission plugins.can_approve can approve versions uploaded by others as long as they are in the list of the plugin owners
- a particular plugin can be deleted and edited only by staff users and plugin owners
- if a user without plugins.can_approve permission uploads a new version, the plugin version is automatically unapproved.
Trust management

Staff members can grant trust to selected plugin creators setting `plugins.can_approve` permission through the front-end application.

The plugin details view offers direct links to grant trust to the plugin creator or the plugin owners.

Validation

Plugin’s metadata are automatically imported and validated from the compressed package when the plugin is uploaded.

Here are some validation rules that you should be aware of when you want to upload a plugin on the official repository:

1. the name of the main folder containing your plugin must contain only ASCII characters (A-Z and a-z), digits and the characters underscore (_) and minus (-), also it cannot start with a digit
2. `metadata.txt` is required
3. all required metadata listed in `metadata table` must be present
4. the `version` metadata field must be unique

Plugin structure

Following the validation rules the compressed (.zip) package of your plugin must have a specific structure to validate as a functional plugin. As the plugin will be unzipped inside the users plugins folder it must have it’s own directory inside the.zip file to not interfere with other plugins. Mandatory files are: `metadata.txt` and `__init__.py`. But it would be nice to have a README and of course an icon to represent the plugin (`resources.qrc`). Following is an example of how a plugin.zip should look like.

```
plugin.zip
 pluginfolder/
  |-- i18n
  |   |-- translation_file_de.ts
  |   |-- img
  |   |-- icon.png
  |   `-- iconsource.svg
  |-- __init__.py
  |-- Makefile
  |-- metadata.txt
  |-- more_code.py
  |-- main_code.py
  |-- README
  |-- resources.qrc
  `-- resources_rc.py
    `-- ui_Qt_user_interface_file.ui
```

It is possible to create plugins in the Python programming language. In comparison with classical plugins written in C++ these should be easier to write, understand, maintain and distribute due to the dynamic nature of the Python language.

Python plugins are listed together with C++ plugins in QGIS plugin manager. They are searched for in `~/ (UserProfile)/python/plugins` and these paths:

- UNIX/Mac: `(gis_prefix)/share/qgis/python/plugins`
- Windows: `(gis_prefix)/python/plugins`

For definitions of `~` and `(UserProfile)` see `core_and_external_plugins`.

Nota: By setting `QGIS_PLUGINPATH` to an existing directory path, you can add this path to the list of paths that are searched for plugins.
Scrierea unui plugin Processing

- Creating from scratch
- Updating a plugin

Depending on the kind of plugin that you are going to develop, it might be a better option to add its functionality as a Processing algorithm (or a set of them). That would provide a better integration within QGIS, additional functionality (since it can be run in the components of Processing, such as the modeler or the batch processing interface), and a quicker development time (since Processing will take of a large part of the work).

To distribute those algorithms, you should create a new plugin that adds them to the Processing Toolbox. The plugin should contain an algorithm provider, which has to be registered when the plugin is instantiated.

### 17.1 Creating from scratch

To create a plugin from scratch which contains an algorithm provider, you can follow these steps using the Plugin Builder:

1. Install the Plugin Builder plugin
2. Creați un plugin nou, utilizând Plugin Builder. În cazul în care Plugin Builder vă cere şablonul de utilizat, selectați „Furnizor Processing”.
3. Plugin-ul creat conține un furnizor cu un singur algoritm. Afișările furnizorului cât și cel al algoritmului sunt complet comentate și conțin informații cu privire la modul de modificare a furnizorului și de adăugare a algoritmilor suplimentari.
17.2 Updating a plugin

If you want to add your existing plugin to Processing, you need to add some code.

1. In your `metadata.txt` file, you need to add a variable:

   ```
   hasProcessingProvider=yes
   ```

2. In the Python file where your plugin is setup with the `initGui` method, you need to adapt some lines like this:

   ```python
   from qgis.core import QgsApplication
   from processing_provider.provider import Provider

   class YourPluginName():
       def __init__(self):
           self.provider = None

       def initProcessing(self):
           self.provider = Provider()
           QgsApplication.processingRegistry().addProvider(self.provider)

       def initGui(self):
           self.initProcessing()

       def unload(self):
           QgsApplication.processingRegistry().removeProvider(self.provider)
   ```

3. You can create a folder `processing_provider` with three files in it:

   - `__init__.py` with nothing in it. This is necessary to make a valid Python package.
   - `provider.py` which will create the Processing provider and expose your algorithms.

   ```python
   from qgis.core import QgsProcessingProvider
   from processing_provider.example_processing_algorithm import ExampleProcessingAlgorithm

   class Provider(QgsProcessingProvider):
       def loadAlgorithms(self, *args, **kwargs):
           self.addAlgorithm(ExampleProcessingAlgorithm())
           # add additional algorithms here
           # self.addAlgorithm(MyOtherAlgorithm())

       def id(self, *args, **kwargs):
           '''The ID of your plugin, used for identifying the provider.
           This string should be a unique, short, character only string, eg "qgis" or "gdal". This string should not be localised.
           '''
           return 'yourplugin'

       def name(self, *args, **kwargs):
           '''The human friendly name of your plugin in Processing.
           This string should be as short as possible (e.g. "Lastools", not "Lastools version 1.0.1 64-bit") and localised.
           '''
           return self.tr('Your plugin')
   ```

(continues on next page)
def icon(self):
    """Should return a QIcon which is used for your provider inside the Processing toolbox."
    """
    return QgsProcessingProvider.icon(self)

• example_processing_algorithm.py which contains the example algorithm file. Copy/paste the content of the script template file and update it according to your needs.

4. Now you can reload your plugin in QGIS and you should see your example script in the Processing toolbox and modeler.

The code snippets on this page need the following imports if you’re outside the pyqgis console:

from qgis.core import 
    QgsVectorLayer,
    QgsPointXY,
The network analysis library can be used to:

- create mathematical graph from geographical data (polyline vector layers)
- implement basic methods from graph theory (currently only Dijkstra’s algorithm)

Biblioteca analizelor de rețea a fost creată prin exportarea funcțiilor de bază ale plugin-ului RoadGraph, iar acum aveți posibilitatea să-i utilizați metodele în plugin-uri sau direct în consola Python.

### 18.1 Informații generale

Pe scurt, un caz tipic de utilizare poate fi descris astfel:

1. crearea grafului din geodate (de obicei un strat vectorial de tip polilinie)
2. rularea analizei grafului
3. folosirea rezultatelor analizei (de exemplu, vizualizarea lor)
18.2 Construirea unui graf

Primul lucru pe care trebuie să-l faceti — este de a pregăti datele de intrare, ceea ce înseamnă conversia stratului vectorial într-un graf. Toate acțiunile viitoare vor folosi acest graf, și nu stratul.

Ca și sursă putem folosi orice strat vectorial de tip polilinie. Nodurile poliliniilor devin noduri ale grafului, segmentele poliliniilor reprezentând marginile grafului. În cazul în care mai multe noduri au același coordonate, atunci ele sunt în același nod al grafului. Astfel, două linii care au un nod comun devin conectate între ele.

În plus, în timpul creării grafului este posibilă “fixarea” („legarea”) de stratul vectorial de intrare a oricărui număr de puncte suplimentare. Pentru fiecare punct suplimentar va fi găsită o potrivire — cel mai apropiat nod sau cea mai apropiată muchie a grafului. În ultimul caz muchia va fi divizată iar nou nod va fi adăugat.

Atributele stratului vectorial și lungimea unei muchii pot fi folosite ca proprietăți ale marginii.

Converting from a vector layer to the graph is done using the Builder programming pattern. A graph is constructed using a so-called Director. There is only one Director for now: QgsVectorLayerDirector. The director sets the basic settings that will be used to construct a graph from a line vector layer, used by the builder to create the graph. Currently, as in the case with the director, only one builder exists: QgsGraphBuilder, that creates QgsGraph objects. You may want to implement your own builders that will build a graphs compatible with such libraries as BGL or NetworkX.

To calculate edge properties the programming pattern strategy is used. For now only QgsNetworkDistanceStrategy strategy (that takes into account the length of the route) and QgsNetworkSpeedStrategy (that also considers the speed) are available. You can implement your own strategy that will use all necessary parameters. For example, RoadGraph plugin uses a strategy that computes travel time using edge length and speed value from attributes.

Este timpul de a aprofunda acest proces.

First of all, to use this library we should import the analysis module

```python
from qgis.analysis import *
```

Apoi, câteva exemple pentru crearea unui director

```python
# don't use information about road direction from layer attributes,
# all roads are treated as two-way
director = QgsVectorLayerDirector(vectorLayer, -1, '', '', '',
                                 QgsVectorLayerDirector.DirectionBoth)

# use field with index 5 as source of information about road direction.
# one-way roads with direct direction have attribute value "yes",
# one-way roads with reverse direction have the value "1", and accordingly
# bidirectional roads have "no". By default roads are treated as two-way.
# This scheme can be used with OpenStreetMap data
director = QgsVectorLayerDirector(vectorLayer, 5, 'yes', '1', 'no',
                                 QgsVectorLayerDirector.DirectionBoth)
```

Pentru a construi un director ar trebui să transmitem stratul vectorial, care va fi folosit ca sursă pentru structura grafului și informațiile despre mișcările permise pe fiecare segment de drum (circulație unilaterală sau bilaterală, sens direct sau invers). Acest apel arată în felul următor

```python
director = QgsVectorLayerDirector(vectorLayer,
                                 directionFieldId, directDirectionValue,
                                 reverseDirectionValue, bothDirectionValue,
                                 defaultDirection)
```

Iată lista completă a ceea ce înseamnă acești parametri:

- `vectorLayer` — vector layer used to build the graph
• `directionFieldId` — indexul câmpului din tabelul de atribute, în care sunt stocate informații despre direcțiile drumurilor. Dacă este -1, atunci aceste informații nu se folosesc deloc. Număr intreg.

• `directDirectionValue` — valoarea câmpului pentru drumurile cu sens direct (trecere de la primul punct de linie la ultimul). Și de caractere.

• `reverseDirectionValue` — valoarea câmpului pentru drumurile cu sens invers (în mișcare de la ultimul punct al liniei până la primul). Și de caractere.

• `bothDirectionValue` — valoarea câmpului pentru drumurile bilaterale (pentru astfel de drumuri putem trece de la primul la ultimul punct și de la ultimul la primul). Și de caractere.

• `defaultDirection` — default road direction. This value will be used for those roads where field `directionFieldId` is not set or has some value different from any of the three values specified above. Possible values are:
  
  - `QgsVectorLayerDirector.DirectionForward` — One-way direct
  
  - `QgsVectorLayerDirector.DirectionBackward` — One-way reverse
  
  - `QgsVectorLayerDirector.DirectionBoth` — Two-way

Este necesară, apoi, crearea unei strategii pentru calcularea proprietăților marginii

```python
# The index of the field that contains information about the edge speed
attributeId = 1

# Default speed value
defaultValue = 50

# Conversion from speed to metric units ('1' means no conversion)
toMetricFactor = 1

strategy = QgsNetworkSpeedStrategy(attributeId, defaultValue, toMetricFactor)
```

Apoi spuneți directorului despre această strategie

```python
director = QgsVectorLayerDirector(vectorLayer, -1, '', '', '', 3)
director.addStrategy(strategy)
```

Now we can use the builder, which will create the graph. The `QgsGraphBuilder` class constructor takes several arguments:

• `crs` — coordinate reference system to use. Mandatory argument.

• `otfEnabled` — use „on the fly” reprojection or no. By default const:`True` (use OTF).

• `topologyTolerance` — topological tolerance. Default value is 0.

• `ellipsoidID` — ellipsoid to use. By default „WGS84”.

```python
# only CRS is set, all other values are defaults
builder = QgsGraphBuilder(vectorLayer.crs())
```

De asemenea, putem defini mai multe puncte, care vor fi utilizate în analiză. De exemplu

```python
startPoint = QgsPointXY(1179720.1871, 5419067.3507)
endPoint = QgsPointXY(1180616.0205, 5419745.7839)
```

Acum că totul este la locul lui, putem să construim graful și să „legăm” aceste puncte la el

```python
tiedPoints = director.makeGraph(builder, [startPoint, endPoint])
```

Construirea unui graf poate dura ceva timp (depinzând de numărul de entități dintr-un strat și de dimensiunea stratului). tiedPoints reprezintă o listă cu coordonatele punctelor „asociate”. Când s-a terminat operaționea de construire putem obține graful și să-l utilizăm pentru analiză

```python
graph = builder.graph()
```

Cu următorul cod putem obține indecșii punctelor noastre

18.2. Construirea unui graf 131
18.3 Analiza grafului

Analiza de rețea este utilizată pentru a găsi răspunsuri la două întrebări: care noduri sunt conectate și identificarea celei mai scurte căi. Pentru a rezolva această problemă, biblioteca de analiză de rețea oferă algoritmul lui Dijkstra.

Algoritmul lui Dijkstra găsește cea mai bună căi între unul dintre vârfurile grafului și toate celelalte, precum și valorile parametrilor de optimizare. Rezultatele pot fi reprezentate ca cel mai scurt arbore.

The shortest path tree is a directed weighted graph (or more precisely a tree) with the following properties:

- doar un singur nod nu are muchii de intrare — rădăcina arborelui
- toate celelalte noduri au numai o margine de intrare
- dacă nodul B este accesibil din nodul A, apoi calea de la A la B este singura disponibilă și este optimă (cea mai scurtă) în acest graf

To get the shortest path tree use the methods shortestTree and dijkstra of the QgsGraphAnalyzer class. It is recommended to use the dijkstra method because it works faster and uses memory more efficiently.

The shortestTree method is useful when you want to walk around the shortest path tree. It always creates a new graph object (QgsGraph) and accepts three variables:

- source — input graph
- startVertexIdx — index of the point on the tree (the root of the tree)
- criterionNum — number of edge property to use (started from 0).

```python
from ... import *
vectorLayer = QgsVectorLayer('testdata/network.gpkg|layername=network_lines', 'lines')
director = QgsVectorLayerDirector(vectorLayer, -1, 'layerName=network_lines', QgsVectorLayerDirector.DirectionBoth)
strategy = QgsNetworkDistanceStrategy()
director.addStrategy(strategy)
builder = QgsGraphBuilder(vectorLayer.crs())
```

Here is some very simple code to display the shortest path tree using the graph created with the shortestTree method (select linestring layer in Layers panel and replace coordinates with your own).

Atenciónare: Use this code only as an example, it creates a lot of QgsRubberBand objects and may be slow on large datasets.

```python
from qgis.core import *
from qgis.gui import *
from qgis.analysis import *
from qgis.QtCore import *
from qgis.QtGui import *
```

(continues on next page)
pStart = QgsPointXY(1179661.925139, 5419188.074362)
tiedPoint = director.makeGraph(builder, [pStart])
pStart = tiedPoint[0]

graph = builder.graph()
idStart = graph.findVertex(pStart)
tree = QgsGraphAnalyzer.shorestTree(graph, idStart, 0)

i = 0
while (i < tree.edgeCount()):
    rb = QgsRubberBand(iface.mapCanvas())
    rb.setColor (Qt.red)
    rb.addPoint (tree.vertex(tree.edge(i).fromVertex()).point())
    rb.addPoint (tree.vertex(tree.edge(i).toVertex()).point())
    i = i + 1

Same thing but using the dijkstra method

```python
from qgis.core import *
from qgis.gui import *
from qgis.analysis import *
from qgis.QtGui import *
from qgis.QtCore import *

vectorLayer = QgsVectorLayer('testdata/network.gpkg|layername=network_lines', 'lines')
director = QgsVectorLayerDirector(vectorLayer, -1, '', '', '',
                                   QgsVectorLayerDirector.DIRECTION_BOTH)
strategy = QgsNetworkDistanceStrategy()
director.addStrategy(strategy)
builder = QgsGraphBuilder(vectorLayer.crs())
pStart = QgsPointXY(1179661.925139, 5419188.074362)
tiedPoint = director.makeGraph(builder, [pStart])
pStart = tiedPoint[0]

graph = builder.graph()
idStart = graph.findVertex(pStart)
(tree, costs) = QgsGraphAnalyzer.dijkstra(graph, idStart, 0)

for edgeId in tree:
    if edgeId == -1:
        continue
    rb = QgsRubberBand(iface.mapCanvas())
    rb.setColor (Qt.red)
    rb.addPoint (graph.vertex(graph.edge(edgeId).fromVertex()).point())
    rb.addPoint (graph.vertex(graph.edge(edgeId).toVertex()).point())
```
To find the optimal path between two points the following approach is used. Both points (start A and end B) are “tied” to the graph when it is built. Then using the shortestTree or dijkstra method we build the shortest path tree with root in the start point A. In the same tree we also find the end point B and start to walk through the tree from point B to point A. The whole algorithm can be written as:

```python
assign T = B
while T != B
    add point T to path
    get incoming edge for point T
    look for point TT, that is start point of this edge
    assign T = TT
    add point A to path
```

În acest moment avem calea, sub formă de listă inversată de noduri (nodurile sunt listate în ordine inversă, de la punctul de final către cel de start), ele fiind vizitate în timpul parcursurii căii.

Here is the sample code for QGIS Python Console (you may need to load and select a linestring layer in TOC and replace coordinates in the code with yours) that uses the shortestTree method.

```python
from qgis.core import *
from qgis.gui import *
from qgis.analysis import *
from qgis.PyQt.QtCore import *
from qgis.PyQt.QtGui import *

vectorLayer = QgsVectorLayer('testdata/network.gpkg|layername=network_lines', 'lines')
bUILDER = QgsGraphBuilder(vectorLayer.sourceCrs())
director = QgsVectorLayerDirector(vectorLayer, '-1', '','','-', QgsVectorLayerDirector.DirectionBoth)
startPoint = QgsPointXY(1179661.925139, 5419188.074362)
endPoint = QgsPointXY(1180942.970617, 5420040.097560)
tiedPoints = director.makeGraph(bUILDER, [startPoint, endPoint])
tStart, tStop = tiedPoints
tStart = director.findVertex(tStart)
tree = QgsGraphAnalyzer.shortestTree(graph, idxStart, 0)
tStart = tree.findVertex(tStart)
tEnd = tree.findVertex(tStop)
if tEnd == -1:
    raise Exception('No route!')

# Add last point
route = [tree.vertex(tEnd).point()]

# Iterate the graph
while tEnd != tStart:
    edgeIds = tree.vertex(tEnd).incomingEdges()
    if len(edgeIds) == 0:
        break
    edge = tree.edge(edgeIds[0])
    route.insert(0, tree.vertex(edge.fromVertex()).point())
    tEnd = edge.fromVertex()
```

(continues on next page)
from qgis.core import *
from qgis.gui import *
from qgis.analysis import *
from qgis.PyQt.QtCore import *
from qgis.PyQt.QtGui import *

vectorLayer = QgsVectorLayer('testdata/network.gpkg|layername=network_lines', 'lines')
director = QgsVectorLayerDirector(vectorLayer, -1, 'linestring', 'linestring', 'linestring', QgsVectorLayerDirector.DirectionBoth)
strategy = QgsNetworkDistanceStrategy()
director.addStrategy(strategy)

builder = QgsGraphBuilder(vectorLayer.sourceCrs())
startPoint = QgsPointXY(1179661.925139, 5419188.074362)
endPoint = QgsPointXY(1180942.970617, 5420040.097560)
tiedPoints = director.makeGraph(builder, [startPoint, endPoint])
tStart, tStop = tiedPoints
graph = builder.graph()
idxStart = graph.findVertex(tStart)
idxEnd = graph.findVertex(tStop)
(tree, costs) = QgsGraphAnalyzer.dijkstra(graph, idxStart, 0)
if tree[idxEnd] == -1:
    raise Exception('No route!')

# Total cost
cost = costs[idxEnd]

# Add last point
route = [graph.vertex(idxEnd).point()]

# Iterate the graph
while idxEnd != idxStart:
    idxEnd = graph.edge(tree[idxEnd]).fromVertex()
    route.insert(0, graph.vertex(idxEnd).point())

# Display
rb = QgsRubberBand(iface.mapCanvas())
rb.setColor(Qt.red)
for p in route:
    rb.addPoint(p)
18.3.2 Ariile de disponibilitate

Aria de disponibilitate a nodului A este un subset de noduri ale graf-ului, care sunt accesibile din nodul A iar costurile căii de la A la aceste noduri nu sunt mai mari decât o anumită valoare.

Mai clar, acest lucru poate fi dovedit cu următorul exemplu: „Există o echipă de intervenție în caz de incendiu. Ce zone ale orașului acoperă această echipă în 5 minute? Dar în 10 minute? Dar în 15 minute?”. Răspunsul la aceste întrebări îl reprezintă zonele de disponibilitate ale echipei de intervenție.

To find the areas of availability we can use the dijkstra method of the QgsGraphAnalyzer class. It is enough to compare the elements of the cost array with a predefined value. If cost[i] is less than or equal to a predefined value, then vertex i is inside the area of availability, otherwise it is outside.

Mai dificilă este oținererea granitelor zonei de disponibilitate. Marginea de jos reprezintă un set de noduri care încă sunt accesibile, iar marginea de sus un set de noduri inaccesibile. De fapt, acest lucru este simplu: marginea disponibilă a atins aceste margini parcurgând arborele cel mai scurt, pentru care nodul de start este accesibil, spre deosebire de celelalt capăt, care nu este accesibil.

Iată un exemplu

```python
director = QgsVectorLayerDirector(vectorLayer, -1, ' ', ' ', ' ',
                                   QgsVectorLayerDirector.DirectionBoth)
strategy = QgsNetworkDistanceStrategy()
director.addStrategy(strategy)
builder = QgsGraphBuilder(vectorLayer.crs())

pStart = QgsPointXY(1179661.925139, 5419188.074362)
delta = iface.mapCanvas().getCoordinateTransform().mapUnitsPerPixel() * 1
rb = QgsRubberBand(iface.mapCanvas(), True)
r.setColor(Qt.green)
rb.addPoint(QgsPointXY(pStart.x() - delta, pStart.y() - delta))
r.addPoint(QgsPointXY(pStart.x() + delta, pStart.y() - delta))
r.addPoint(QgsPointXY(pStart.x() + delta, pStart.y() + delta))
r.addPoint(QgsPointXY(pStart.x() - delta, pStart.y() + delta))
tiedPoints = director.makeGraph(builder, [pStart])
graph = builder.graph()
tStart = tiedPoints[0]
idStart = graph.findVertex(tStart)
(tree, cost) = QgsGraphAnalyzer.dijkstra(graph, idStart, 0)
upperBound = []
r = 1500.0
i = 0
tree.reverse()

while i < len(cost):
    if cost[i] > r and tree[i] != -1:
        outVertexId = graph.edge(tree[i]).toVertex()
        if cost[outVertexId] < r:
            upperBound.append(i)
        i = i + 1

for i in upperBound:
```

(continues on next page)
centerPoint = graph.vertex(i).point()
rb = QgsRubberBand(iface.mapCanvas(), True)
rb.setColor(Qt.red)
rb.addPoint(QgsPointXY(centerPoint.x() - delta, centerPoint.y() - delta))
r.addPoint(QgsPointXY(centerPoint.x() + delta, centerPoint.y() - delta))
r.addPoint(QgsPointXY(centerPoint.x() + delta, centerPoint.y() + delta))
r.addPoint(QgsPointXY(centerPoint.x() - delta, centerPoint.y() + delta))
QGIS Server and Python

19.1 Introducere

QGIS Server is three different things:

1. QGIS Server library: a library that provides an API for creating OGC web services
2. QGIS Server FCGI: a FCGI binary application qgis_maserv.fcgi that together with a web server implements a set of OGC services (WMS, WFS, WCS etc.) and OGC APIs (WFS3/OAPIF)
3. QGIS Development Server: a development server binary application qgis_mapserver that implements a set of OGC services (WMS, WFS, WCS etc.) and OGC APIs (WFS3/OAPIF)

This chapter of the cookbook focuses on the first topic and by explaining the usage of QGIS Server API it shows how it is possible to use Python to extend, enhance or customize the server behavior or how to use the QGIS Server API to embed QGIS server into another application.

There are a few different ways you can alter the behavior of QGIS Server or extend its capabilities to offer new custom services or APIs, these are the main scenarios you may face:

- EMBEDDING → Use QGIS Server API from another Python application
- STANDALONE → Run QGIS Server as a standalone WSGI/HTTP service
- FILTERS → Enhance/Customize QGIS Server with filter plugins
- SERVICES → Add a new SERVICE
- OGC APIs → Add a new OGC API

Embeding and standalone applications require using the QGIS Server Python API directly from another Python script or application while the remaining options are better suited for when you want to add custom features to a standard QGIS Server binary application (FCGI or development server): in this case you’ll need to write a Python plugin for the server application and register your custom filters, services or APIs.
19.2 Server API basics

The fundamental classes involved in a typical QGIS Server application are:

- `QgsServer` the server instance (typically a single instance for the whole application life)
- `QgsServerRequest` the request object (typically recreated on each request)
- `QgsServerResponse` the response object (typically recreated on each request)
- `QgsServer.handleRequest(request, response)` processes the request and populates the response

The QGIS Server FCGI or development server workflow can be summarized as follows:

```python
initialize the QgsApplication
create the QgsServer
the main server loop waits forever for client requests:
  for each incoming request:
    create a QgsServerRequest request
    create a QgsServerResponse response
    call QgsServer.handleRequest(request, response)
    filter plugins may be executed
    send the output to the client
```

Inside the `QgsServer.handleRequest(request, response)` method the filter plugins callbacks are called and `QgsServerRequest` and `QgsServerResponse` are made available to the plugins through the `QgsServerInterface`.

**Atención:** QGIS server classes are not thread safe, you should always use a multiprocessing model or containers when building scalable applications based on QGIS Server API.

19.3 Standalone or embedding

For standalone server applications or embedding, you will need to use the above mentioned server classes directly, wrapping them up into a web server implementation that manages all the HTTP protocol interactions with the client.

A minimal example of the QGIS Server API usage (without the HTTP part) follows:

```python
from qgis.core import QgsApplication
from qgis.server import *

app = QgsApplication([], False)
server = QgsServer()

# Create the server instance, it may be a single one that
# is reused on multiple requests
server = QgsServer()

# Create the request by specifying the full URL and an optional body
# (for example for POST requests)
request = QgsBufferServerRequest(
    'http://localhost:8081/?MAP=/qgis-server/projects/helloworld.qgs' +
    '&SERVICE=WMS&REQUEST=GetCapabilities')

# Create a response objects
response = QgsBufferServerResponse()

# Handle the request
server.handleRequest(request, response)
```

(continues on next page)
Here is a complete standalone application example developed for the continuous integrations testing on QGIS source code repository, it showcases a wide set of different plugin filters and authentication schemes (not mean for production because they were developed for testing purposes only but still interesting for learning):

https://github.com/qgis/QGIS/blob/master/tests/src/python/qgis_wrapped_server.py

### 19.4 Server plugins

Server python plugins are loaded once when the QGIS Server application starts and can be used to register filters, services or APIs.

The structure of a server plugin is very similar to their desktop counterpart, a `QgsServerInterface` object is made available to the plugins and the plugins can register one or more custom filters, services or APIs to the corresponding registry by using one of the methods exposed by the server interface.

#### 19.4.1 Server filter plugins

Filters come in three different flavors and they can be instantiated by subclassing one of the classes below and by calling the corresponding method of `QgsServerInterface`:

<table>
<thead>
<tr>
<th>Filter Type</th>
<th>Base Class</th>
<th><code>QgsServerInterface</code> registration</th>
</tr>
</thead>
<tbody>
<tr>
<td>I/O</td>
<td><code>QgsServerFilter</code></td>
<td><code>registerFilter</code></td>
</tr>
<tr>
<td>Access Control</td>
<td><code>QgsAccessControlFilter</code></td>
<td><code>registerAccessControl</code></td>
</tr>
<tr>
<td>Cache</td>
<td><code>QgsServerCacheFilter</code></td>
<td><code>registerServerCache</code></td>
</tr>
</tbody>
</table>

### I/O filters

I/O filters can modify the server input and output (the request and the response) of the core services (WMS, WFS etc.) allowing to do any kind of manipulation of the services workflow, it is possible for example to restrict the access to selected layers, to inject an XSL stylesheet to the XML response, to add a watermark to a generated WMS image and so on.

From this point, you might find useful a quick look to the server plugins API docs.

Each filter should implement at least one of three callbacks:

- `requestReady()`
- `responseComplete()`
- `sendResponse()`

All filters have access to the request/response object (`QgsRequestHandler`) and can manipulate all its properties (input/output) and raise exceptions (while in a quite particular way as we’ll see below).

Here is the pseudo code showing how the server handles a typical request and when the filter’s callbacks are called:
if SERVICE is WMS/WFS/WCS:
create WMS/WFS/WCS service
call service's executeRequest
    possibly call sendResponse for each chunk of bytes
    sent to the client by a streaming services (WFS)
call responseComplete
call sendResponse
request handler sends the response to the client

Următoarele paragrafe descriu, în detaliu, funcțiile de reapelare disponibile.

**requestReady**

Este apelată atunci când cererea este pregătită: adresa și datele primite au fost analizate și, înainte de a intra în comutatorul serviciilor de bază (WMS, WFS, etc), acesta este punctul în care se poate interveni asupra datelor de intrare, putându-se efectua acțiuni de genul:

- autentificare/autorizare
- redirectări
- adăugarea/eliminarea anumitor parametri (denumirile tipurilor, de exemplu)
- tratarea excepțiilor

Ați putea chiar să substituiți în întregime un serviciu de bază, prin schimbarea parametrului `SERVICE`, astfel, ocolindu-se complet serviciul de bază (deși, acest lucru nu ar avea prea mult sens).

**sendResponse**

This is called whenever any output is sent to FCGI `stdout` (and from there, to the client), this is normally done after core services have finished their process and after `responseComplete` hook was called, but in a few cases XML can become so huge that a streaming XML implementation was needed (WFS GetFeature is one of them), in this case, `sendResponse` is called multiple times before the response is complete (and before `responseComplete` is called). The obvious consequence is that `sendResponse` is normally called once but might be exceptionally called multiple times and in that case (and only in that case) it is also called before `responseComplete`.

`sendResponse` is the best place for direct manipulation of core service's output and while `responseComplete` is typically also an option, `sendResponse` is the only viable option in case of streaming services.

**responseComplete**

This is called once when core services (if hit) finish their process and the request is ready to be sent to the client. As discussed above, this is normally called before `sendResponse` except for streaming services (or other plugin filters) that might have called `sendResponse` earlier.

`responseComplete` is the ideal place to provide new services implementation (WPS or custom services) and to perform direct manipulation of the output coming from core services (for example to add a watermark upon a WMS image).
Raising exceptions from a plugin

Some work has still to be done on this topic: the current implementation can distinguish between handled and unhandled exceptions by setting a `QgsRequestHandler` property to an instance of `QgsMapServiceException`, this way the main C++ code can catch handled python exceptions and ignore unhandled exceptions (or better: log them).

Această abordare funcționează în principiu, dar nu este în spiritul limbajului „python”: o abordare mai bună ar fi de a face vizibile exceptiile din codul python la nivelul buclei C++, pentru a fi manipulată acolo.

scrierea unui plugin pentru server

A server plugin is a standard QGIS Python plugin as described in Developing Python Plugins, that just provides an additional (or alternative) interface: a typical QGIS desktop plugin has access to QGIS application through the `QgsInterface` instance, a server plugin has only access to a `QgsServerInterface` when it is executed within the QGIS Server application context.

To make QGIS Server aware that a plugin has a server interface, a special metadata entry is needed (in `metadata.txt`)

```plaintext
server=True
```

**Important:** Only plugins that have the `server=True` metadata set will be loaded and executed by QGIS Server.

The example plugin discussed here (with many more) is available on github at https://github.com/elpaso/qgis3-server-vagrant/tree/master/resources/web/plugins, a few server plugins are also published in the official QGIS plugins repository.

Fișierele Plugin-ului

Iată structura de directoare a exemplului nostru de plugin pentru server

```plaintext
PYTHON_PLUGINS_PATH/
HelloServer/
  __init__.py --> *required*
  HelloServer.py --> *required*
  metadata.txt --> *required*
```

`__init__.py`

This file is required by Python's import system. Also, QGIS Server requires that this file contains a `serverClassFactory()` function, which is called when the plugin gets loaded into QGIS Server when the server starts. It receives reference to instance of `QgsServerInterface` and must return instance of your plugin's class. This is how the example plugin `__init__.py` looks like

```python
def serverClassFactory(serverIface):
    from .HelloServer import HelloServerServer
    return HelloServerServer(serverIface)
```
HelloServer.py

Aici este locul în care se întâmplă magia, și iată rezultatul acesteia: (de exemplu HelloServer.py)

A server plugin typically consists in one or more callbacks packed into instances of a QgsServerFilter. Each QgsServerFilter implements one or more of the following callbacks:

- requestReady()
- responseComplete()
- sendResponse()

The following example implements a minimal filter which prints HelloServer! in case the SERVICE parameter equals to “HELLO”

```python
class HelloFilter(QgsServerFilter):
    def __init__(self, serverIface):
        super().__init__(serverIface)

    def requestReady(self):
        QgsMessageLog.logMessage("HelloFilter.requestReady")

    def sendResponse(self):
        QgsMessageLog.logMessage("HelloFilter.sendResponse")

    def responseComplete(self):
        QgsMessageLog.logMessage("HelloFilter.responseComplete")
        params = self.serverInterface().requestHandler().requestMap()
        if params.get('SERVICE', '').upper() == 'HELLO':
            request.clear()
            request.setResponseHeader('Content-type', 'text/plain')
            request.appendBody(b'HelloServer!')
```

The filters must be registered into the serverIface as in the following example:

```python
class HelloServerServer:
    def __init__(self, serverIface):
        serverIface.registerFilter(HelloFilter(), 100)
```

The second parameter of registerFilter sets a priority which defines the order for the callbacks with the same name (the lower priority is invoked first).

By using the three callbacks, plugins can manipulate the input and/or the output of the server in many different ways. In every moment, the plugin instance has access to the QgsRequestHandler through the QgsServerInterface. The QgsRequestHandler class has plenty of methods that can be used to alter the input parameters before entering the core processing of the server (by using requestReady()) or after the request has been processed by the core services (by using sendResponse()).

Următorul exemplu demonstrează câteva cazuri de utilizare obișnuită:
Modificarea intrării

The example plugin contains a test example that changes input parameters coming from the query string, in this example a new parameter is injected into the (already parsed) `parameterMap`, this parameter is then visible by core services (WMS etc.), at the end of core services processing we check that the parameter is still there:

```python
class ParamsFilter(QgsServerFilter):
    def __init__(self, serverIface):
        super(ParamsFilter, self).__init__(serverIface)

    def requestReady(self):
        request = self.serverInterface().requestHandler()
        params = request.parameterMap()
        request.setParameter('TEST_NEW_PARAM', 'ParamsFilter')

    def responseComplete(self):
        request = self.serverInterface().requestHandler()
        params = request.parameterMap()
        if params.get('TEST_NEW_PARAM') == 'ParamsFilter':
            QgsMessageLog.logMessage("SUCCESS - ParamsFilter.responseComplete")
        else:
            QgsMessageLog.logMessage("FAIL - ParamsFilter.responseComplete")
```

This is an extract of what you see in the log file:

```
src/core/qgsmessagelog.cpp: 45: (logMessage) [0ms] 2014-12-12T12:39:29 plugin[0]←
   ←Server plugin HelloServer loaded!
src-core/qgsmessagelog.cpp: 45: (logMessage) [0ms] 2014-12-12T12:39:29 Server[0]←
   ←Server python plugins loaded
src/mapserver/qgshttprequesthandler.cpp: 547: (requestStringToParameterMap) [1ms]←
   ←inserting pair SERVICE // HELLO into the parameter map
src/mapserver/qgsserverfilter.cpp: 42: (requestReady) [0ms] QgsServerFilter←
   ←default requestReady called
src/core/qgsmessagelog.cpp: 45: (logMessage) [0ms] 2014-12-12T12:39:29 plugin[0]←
   ←SUCCESS - ParamsFilter.responseComplete
```

On the highlighted line the “SUCCESS” string indicates that the plugin passed the test.

Acestor tehnica poate fi exploataat pentru a utiliza un serviciu personalizat in locul unuia de bază: de exemplu, ati putea sari peste o cerere WFS SERVICE, sau peste oricare altă cerere de bază, doar prin schimbarea parametrului SERVICE în ceva diferit, iar serviciul de bază va fi omis; în acel caz, veți putea injecta datele dvs. în interiorul rezultatului, trimițându-le clientului (acest lucru este explicat în continuare).

**Sfat:** If you really want to implement a custom service it is recommended to subclass `QgsService` and register your service on `registerFilter` by calling its `registerService(service)`
The watermark filter example shows how to replace the WMS output with a new image obtained by adding a water-
mark image on the top of the WMS image generated by the WMS core service:

```python
from qgis.server import *
from qgis.PyQt.QtCore import *
from qgis.PyQt.QtGui import *

class WatermarkFilter(QgsServerFilter):
    def __init__(self, serverIface):
        super().__init__(serverIface)

    def responseComplete(self):
        request = self.serverInterface().requestHandler()
        params = request.parameterMap()
        # Do some checks
        if (params.get('SERVICE').upper() == 'WMS' 
            and params.get('REQUEST').upper() == 'GETMAP' 
            and not request.exceptionRaised()):
            QgsMessageLog.logMessage("WatermarkFilter.responseComplete: image ready %s" % request.parameter("FORMAT"))
            # Get the image
            img = QImage()
            img.loadFromData(request.body())
            # Adds the watermark
            watermark = QImage(os.path.join(os.path.dirname(__file__), 'media/watermark.png'))
            p = QPainter(img)
            p.drawImage(QRect(20, 20, 40, 40), watermark)
            p.end()
            ba = QByteArray()
            buffer = QBuffer(ba)
            buffer.open(QIODevice.WriteOnly)
            img.save(buffer, "PNG" if "png" in request.parameter("FORMAT") else "JPG")
            # Set the body
            request.clearBody()
            request.appendBody(ba)
```

In this example the SERVICE parameter value is checked and if the incoming request is a WMS GETMAP and
no exceptions have been set by a previously executed plugin or by the core service (WMS in this case), the WMS
generated image is retrieved from the output buffer and the watermark image is added. The final step is to clear the
output buffer and replace it with the newly generated image. Please note that in a real-world situation we should also
check for the requested image type instead of supporting PNG or JPG only.

**Access control filters**

Access control filters gives the developer a fine-grained control over which layers, features and attributes can be
accessed, the following callbacks can be implemented in an access control filter:

- layerFilterExpression(layer)
- layerFilterSubsetString(layer)
- layerPermissions(layer)
- authorizedLayerAttributes(layer, attributes)
- allowToEdit(layer, feature)
- cacheKey()
Fișierele Plugin-ului

Here’s the directory structure of our example plugin:

```python
PYTHON_PLUGINS_PATH/
   MyAccessControl/
      __init__.py  --> *required*
      AccessControl.py  --> *required*
      metadata.txt  --> *required*
```

__init__.py

This file is required by Python’s import system. As for all QGIS server plugins, this file contains a `serverClassFactory()` function, which is called when the plugin gets loaded into QGIS Server at startup. It receives a reference to an instance of `QgsServerInterface` and must return an instance of your plugin’s class. This is how the example plugin __init__.py looks like:

```python
def serverClassFactory(serverIface):
    from MyAccessControl.AccessControl import AccessControlServer
    return AccessControlServer(serverIface)
```

AccessControl.py

```python
class AccessControlFilter(QgsAccessControlFilter):
    def __init__(self, server_iface):
        super().__init__(server_iface)

    def layerFilterExpression(self, layer):
        """ Return an additional expression filter """
        return super().layerFilterExpression(layer)

    def layerFilterSubsetString(self, layer):
        """ Return an additional subset string (typically SQL) filter """
        return super().layerFilterSubsetString(layer)

    def layerPermissions(self, layer):
        """ Return the layer rights """
        return super().layerPermissions(layer)

    def authorizedLayerAttributes(self, layer, attributes):
        """ Return the authorised layer attributes """
        return super().authorizedLayerAttributes(layer, attributes)

    def allowToEdit(self, layer, feature):
        """ Are we authorise to modify the following geometry """
        return super().allowToEdit(layer, feature)

    def cacheKey(self):
        return super().cacheKey()

class AccessControlServer:
    def __init__(self, serverIface):
        """ Register AccessControlFilter """
        serverIface.registerAccessControl(AccessControlFilter(self.serverIface), 100)
```

Acest exemplu oferă un acces deplin pentru oricine.
Este de datoria plugin-ului să știe cine este conectat.
Toate aceste metode au ca argument stratul, pentru a putea personaliza restricțiile pentru fiecare strat.

**layerFilterExpression**

Se folosește pentru a adăuga o Expresie de limitare a rezultatelor, ex.:

```python
def layerFilterExpression(self, layer):
    return "$role = 'user'"
```

Pentru restrângerea la entitățile pentru care atributul „rol” are valoarea „user”.

**layerFilterSubsetString**

La fel ca și precedenta, dar folosește SubsetString (executată în baza de date)

```python
def layerFilterSubsetString(self, layer):
    return "role = 'user'"
```

Pentru restrângerea la entitățile pentru care atributul „rol” are valoarea „user”.

**layerPermissions**

Limitează accesul la strat.

Return an object of type LayerPermissions, which has the properties:

• canRead to see it in the GetCapabilities and have read access.
• canInsert to be able to insert a new feature.
• canUpdate to be able to update a feature.
• canDelete to be able to delete a feature.

Exemplu:

```python
def layerPermissions(self, layer):
    rights = QgsAccessControlFilter.LayerPermissions()
    rights.canRead = True
    rights.canInsert = rights.canUpdate = rights.canDelete = False
    return rights
```

Pentru a permite tuturor accesul numai pentru citire.

**authorizedLayerAttributes**

Folosit pentru a reduce vizibilitatea unui subset specific de atribute.

Atributul argument returnează setul actual de atribute vizibile.

Exemplu:

```python
def authorizedLayerAttributes(self, layer, attributes):
    return [a for a in attributes if a != "role"]
```

Pentru a ascunde atributul «role».
allowToEdit

Se folosește pentru a limita editarea unui subset specific de entități.
Este folosit în protocolul WFS-Transaction.
Exemplu:

```python
def allowToEdit(self, layer, feature):
    return feature.attribute('role') == 'user'
```

Pentru a putea modifica numai entitatea pentru care atributul „rol” are valoarea de „utilizator”.

cacheKey

Serverul QGIS mentine o memorie tampon a capabilităților, de aceea, pentru a avea o memorie cache pentru fiecare rol, puteți specifica rolul cu ajutorul acestei metode. Sau puteți seta valoarea None, pentru a dezactiva complet memoria tampon.

19.4.2 Custom services

In QGIS Server, core services such as WMS, WFS and WCS are implemented as subclasses of `QgsService`.
To implemented a new service that will be executed when the query string parameter SERVICE matches the service name, you can implemented your own `QgsService` and register your service on the `serviceRegistry` by calling its `registerService(service)`.

Here is an example of a custom service named CUSTOM:

```python
from qgis.server import QgsService
from qgis.core import QgsMessageLog

class CustomServiceService(QgsService):
    def __init__(self):
        QgsService.__init__(self)
    def name(self):
        return "CUSTOM"
    def version(self):
        return "1.0.0"
    def allowMethod(method):
        return True
    def executeRequest(self, request, response, project):
        response.setStatusCode(200)
        QgsMessageLog.logMessage('Custom service executeRequest')
        response.write("Custom service executeRequest")

class CustomService():
    def __init__(self, serverIface):
        serverIface.serviceRegistry().registerService(CustomServiceService())
```

19.4. Server plugins 149
19.4.3 Custom APIs

In QGIS Server, core OGC APIs such as OAPIF (aka WFS3) are implemented as collections of `QgsServerOgcApiHandler` subclasses that are registered to an instance of `QgsServerOgcApi` (or its parent class `QgsServerApi`).

To implement a new API that will be executed when the URL path matches a certain URL, you can implement your own `QgsServerOgcApiHandler` instances, add them to an `QgsServerOgcApi` and register the API on the `serviceRegistry` by calling its `registerApi(api)`.

Here is an example of a custom API that will be executed when the URL contains `/customapi`:

```python
import json
import os

from qgis.PyQt.QtCore import QBuffer, QIODevice, QTextStream, QRegularExpression
from qgis.server import QgsServiceRegistry, QgsService, QgsServerFilter, QgsServerOgcApi, QgsServerQueryQStringParameter, QgsServerOgcApiHandler,
from qgis.core import QgsMessageLog, QgsJsonExporter, QgsCircle, QgsFeature, QgsPoint, QgsGeometry,

class CustomApiHandler(QgsServerOgcApiHandler):
    def __init__(self):
        super(CustomApiHandler, self).__init__()
        self.setContentTypes([QgsServerOgcApi.HTML, QgsServerOgcApi.JSON])

    def path(self):
        return QRegularExpression("/customapi")

    def operationId(self):
        return "CustomApiXYCircle"

    def summary(self):
        return "Creates a circle around a point"

    def description(self):
        return "Creates a circle around a point"

    def linkTitle(self):
        return "Custom Api XY Circle"

    def linkType(self):
        return QgsServerOgcApi.data

    def handleRequest(self, context):
        """Simple Circle""
        values = self.values(context)
```

(continues on next page)
x = values['x']
y = values['y']
r = values['r']
f = QgsFeature()
f.setAttributes([x, y, r])
f.setGeometry(QgsCircle(QgsPoint(x, y), r).toCircularString())
exporter = QgsJsonExporter()
self.write(json.loads(exporter.exportFeature(f)), context)

def templatePath(self, context):
    # The template path is used to serve HTML content
    return os.path.join(os.path.dirname(__file__), 'circle.html')

def parameters(self, context):
    return [QgsServerQueryStringParameter('x', True, QgsServerQueryStringParameter.Type.Double, 'X coordinate'),
            QgsServerQueryStringParameter('y', True, QgsServerQueryStringParameter.Type.Double, 'Y coordinate'),
            QgsServerQueryStringParameter('r', True, QgsServerQueryStringParameter.Type.Double, 'radius')]

class CustomApi():
    def __init__(self, serverIface):
        api = QgsServerOgcApi(serverIface, '/customapi',
                              'custom api', 'a custom api', '1.1')
        handler = CustomApiHandler()
        api.registerHandler(handler)
        serverIface.serviceRegistry().registerApi(api)

from qgis.PyQt.QtCore import (QRectF,)

from qgis.core import (QgsProject,
                        QgsLayerTreeModel,)

from qgis.gui import (QgsLayerTreeView,
                      )

19.4. Server plugins
20.1 Interfața cu Utilizatorul

Change Look & Feel

```
from qgis.PyQt.QtWidgets import QApplication

app = QApplication.instance()
app.setStyleSheet(".QWidget {color: blue; background-color: yellow;}")
# You can even read the stylesheet from a file
with open("testdata/file.qss") as qss_file_content:
    app.setStyleSheet(qss_file_content.read())
```

Change icon and title

```
from qgis.PyQt.QtGui import QIcon

icon = QIcon("/path/to/logo/file.png")
iface.mainWindow().setWindowIcon(icon)
iface.mainWindow().setWindowTitle("My QGIS")
```

20.2 Setări

Get QgsSettings list

```
from qgis.core import QgsSettings

qs = QgsSettings()
for k in sorted(qs.allKeys()):
    print (k)
```
### 20.3 Bare de instrumente

Remove toolbar

```python
toolbar = iface.helpToolBar()
parent = toolbar.parentWidget()
parent.removeToolBar(toolbar)

# and add again
parent.addToolBar(toolbar)
```

Remove actions toolbar

```python
actions = iface.attributesToolBar().actions()
iface.attributesToolBar().clear()
iface.attributesToolBar().addAction(actions[4])
iface.attributesToolBar().addAction(actions[3])
```

### 20.4 Menus

Remove menu

```python
# for example Help Menu
menu = iface.helpMenu()
menubar = menu.parentWidget()
menubar.removeAction(menu.menuAction())

# and add again
menubar.addAction(menu.menuAction())
```

### 20.5 Canevasul

Access canvas

```python
canvas = iface.mapCanvas()
```

Change canvas color

```python
from qgis.Qt.QtCore import Qt
iface.mapCanvas().setCanvasColor(Qt.black)
iface.mapCanvas().refresh()
```

Map Update interval

```python
from qgis.core import QgsSettings
# Set milliseconds (150 milliseconds)
QgsSettings().setValue("/qgis/map_update_interval", 150)
```
20.6. Straturile

Add vector layer

```python
layer = iface.addVectorLayer("testdata/airports.shp", "layer name you like", "ogr")
if not layer or not layer.isValid():
    print("Layer failed to load!")
```

Get active layer

```python
layer = iface.activeLayer()
```

List all layers

```python
from qgis.core import QgsProject
QgsProject.instance().mapLayers().values()
```

Obtain layers name

```python
from qgis.core import QgsVectorLayer
layer = QgsVectorLayer("Point?crs=EPSG:4326", "layer name you like", "memory")
QgsProject.instance().addMapLayer(layer)
layers_names = []
for layer in QgsProject.instance().mapLayers().values():
    layers_names.append(layer.name())
print("layers TOC = ").format(layers_names)
```

Otherwise

```python
layers_names = [layer.name() for layer in QgsProject.instance().mapLayers().values()]
print("layers TOC = ").format(layers_names)
```

Find layer by name

```python
from qgis.core import QgsProject
layer = QgsProject.instance().mapLayersByName("layer name you like")[0]
print(layer.name())
```

Set active layer

```python
from qgis.core import QgsProject
layer = QgsProject.instance().mapLayersByName("layer name you like")[0]
iface.setActiveLayer(layer)
```

Refresh layer at interval

```python
from qgis.core import QgsProject
```

(continues on next page)
layer = QgsProject.instance().mapLayersByName("layer name you like")[0]
# Set seconds (5 seconds)
layer.setAutoRefreshInterval(5000)
# Enable auto refresh
layer.setAutoRefreshEnabled(True)

Show methods
dir(layer)

Adding new feature with feature form

```python
from qgis.core import QgsFeature, QgsGeometry
feat = QgsFeature()
geom = QgsGeometry()
feat.setGeometry(geom)
feat.setFields(layer.fields())
iface.openFeatureForm(layer, feat, False)
```

Adding new feature without feature form

```python
from qgis.core import QgsGeometry, QgsPointXY, QgsFeature
pr = layer.dataProvider()
feat = QgsFeature()
feat.setGeometry(QgsGeometry.fromPointXY(QgsPointXY(10, 10)))
pr.addFeatures([feat])
```

Get features

```python
for f in layer.getFeatures():
    print (f)
```

Get selected features

```python
for f in layer.selectedFeatures():
    print (f)
```

Get selected features Ids

```python
selected_ids = layer.selectedFeatureIds()
print(selected_ids)
```

Create a memory layer from selected features Ids

```python
from qgis.core import QgsFeatureRequest
memory_layer = layer.materialize(QgsFeatureRequest().setFilterFids(layer.
    selectedFeatureIds()))
QgsProject.instance().addMapLayer(memory_layer)
```

Get geometry

```python
# Point layer
for f in layer.getFeatures():
    geom = f.geometry()
    print ('%f, %f' % (geom.asPoint().y(), geom.asPoint().x()))
```
Move geometry

```python
from qgis.core import QgsFeature, QgsGeometry
poly = QgsFeature()
geom = QgsGeometry.fromWkt("POINT(7 45)")
geom.translate(1, 1)
poly.setGeometry(geom)
print(poly.geometry())
```

Set the CRS

```python
from qgis.core import QgsProject, QgsCoordinateReferenceSystem
for layer in QgsProject.instance().mapLayers().values():
    layer.setCrs(QgsCoordinateReferenceSystem('EPSG:4326'))
```

See the CRS

```python
from qgis.core import QgsProject
for layer in QgsProject.instance().mapLayers().values():
    crs = layer.crs().authid()
    layer.setName('{} ({})'.format(layer.name(), crs))
```

Hide a field column

```python
from qgis.core import QgsEditorWidgetSetup
def fieldVisibility(layer, fname):
    setup = QgsEditorWidgetSetup('Hidden', {})
    for i, column in enumerate(layer.fields()):
        if column.name() == fname:
            layer.setEditorWidgetSetup(i, setup)
        break
    else:
        continue
```

Layer from WKT

```python
from qgis.core import QgsVectorLayer, QgsFeature, QgsGeometry, QgsProject
layer = QgsVectorLayer("Polygon?crs=epsg:4326", 'Mississippi', 'memory')
pr = layer.dataProvider()
poly = QgsFeature()
geom = QgsGeometry.fromWkt("POLYGON ((-88.82 34.99,-88.0934.89,-88.39 30.34,-89.57
                     -30.18,-89.73 31,-91.63 30.99,-90.8732.37,-91.23 33.44,-90.93 34.23,-90.30 34.99,-
                     -88.82 34.99))")
poly.setGeometry(geom)
pr.addFeatures([poly])
layer.updateExtents()
QgsProject.instance().addMapLayers([layer])
```

Load all vector layers from GeoPackage

```python
(fileName = "testdata/sublayers.gpkg"
layer = QgsVectorLayer(fileName, "test", "ogr")
subLayers = layer.dataProvider().subLayers()
```

(continues on next page)
**PyQGIS 3.10 developer cookbook**

(continuare din pagina precedentă)

```python
for subLayer in subLayers:
    name = subLayer.split('::!')[1]
    uri = "%s|layername=%s" % (fileName, name)
    # Create layer
    sub_vlayer = QgsVectorLayer(uri, name, 'ogr')
    # Add layer to map
    QgsProject.instance().addMapLayer(sub_vlayer)
```

**Load tile layer (XYZ-Layer)**

```python
from qgis.core import QgsRasterLayer, QgsProject

def loadXYZ(url, name):
    rasterLyr = QgsRasterLayer("type=xyz&url=" + url, name, "wms")
    QgsProject.instance().addMapLayer(rasterLyr)

urlWithParams = 'type=xyz&url=https://a.tile.openstreetmap.org/%7Bz%7D/%7Bx%7D/%7By.png&max=19&zmin=0&crs=EPSG3857'
loadXYZ(urlWithParams, 'OpenStreetMap')
```

**Remove all layers**

QgsProject.instance().removeAllMapLayers()

**Remove all**

QgsProject.instance().clear()

### 20.7 Table of contents

**Access checked layers**

```python
iface.mapCanvas().layers()
```

**Remove contextual menu**

```python
ltv = iface.layerTreeView()
mp = ltv.menuProvider()
ltv.setMenuProvider(None)
# Restore
ltv.setMenuProvider(mp)
```

### 20.8 Advanced TOC

**Root node**

```python
from qgis.core import QgsVectorLayer, QgsProject, QgsLayerTreeLayer

root = QgsProject.instance().layerTreeRoot()
node_group = root.addGroup("My Group")
layer = QgsVectorLayer("Point?crs=EPSG:4326", "layer name you like", "memory")
QgsProject.instance().addMapLayer(layer, False)
```

(continues on next page)
node_group.addLayer(layer)
print(root)
print(root.children())

Access the first child node

```python
from qgis.core import QgsLayerTreeGroup, QgsLayerTreeLayer, QgsLayerTree
child0 = root.children()[0]
print(child0.name())
print(type(child0))
print(isinstance(child0, QgsLayerTreeLayer))
print(isinstance(child0.parent(), QgsLayerTree))
```

My Group
<class 'qgis._core.QgsLayerTreeGroup'>
False
True

Find groups and nodes

```python
from qgis.core import QgsLayerTreeGroup, QgsLayerTreeLayer

def get_group_layers(group):
    print("- group: " + group.name())
    for child in group.children():
        if isinstance(child, QgsLayerTreeGroup):
            get_group_layers(child)
        else:
            print("- layer: " + child.name())

root = QgsProject.instance().layerTreeRoot()
for child in root.children():
    if isinstance(child, QgsLayerTreeGroup):
        get_group_layers(child)
    elif isinstance(child, QgsLayerTreeLayer):
        print("- layer: " + child.name())
```

- group: My Group
- layer: layer name you like

Find group by name

```python
print(root.findGroup("My Group"))
```

<qgis._core.QgsLayerTreeGroup object at 0x7fd75560cee8>

Find layer by id

```python
print(root.findLayer(layer.id()))
```

<qgis._core.QgsLayerTreeLayer object at 0x7f56087af288>

Add layer
```
from qgis.core import QgsVectorLayer, QgsProject

layer1 = QgsVectorLayer("Point?crs=EPSG:4326", "layer name you like 2", "memory")
QgsProject.instance().addMapLayer(layer1, False)
node_layer1 = root.addLayer(layer1)

# Remove it
QgsProject.instance().removeMapLayer(layer1)
```

**Add group**
```
from qgis.core import QgsLayerTreeGroup

node_group2 = QgsLayerTreeGroup("Group 2")
root.addChildNode(node_group2)
QgsProject.instance().mapLayersByName("layer name you like")
```

**Move loaded layer**
```
layer = QgsProject.instance().mapLayersByName("layer name you like")
root = QgsProject.instance().layerTreeRoot()
myLayer = root.findLayer(layer.id())
myClone = myLayer.clone()
parent = myLayer.parent()

myGroup = root.findGroup("My Group")
# Insert in first position
myGroup.insertChildNode(0, myClone)
parent.removeChildNode(myLayer)
```

**Move loaded layer to a specific group**
```
QgsProject.instance().addMapLayer(layer, False)

root = QgsProject.instance().layerTreeRoot()
myGroup = root.findGroup("My Group")
myOriginalLayer = root.findLayer(layer.id())
myLayer = myOriginalLayer.clone()
myGroup.insertChildNode(0, myLayer)
parent.removeChildNode(myOriginalLayer)
```

**Changing visibility**
```
myGroup.setItemVisibilityChecked(False)
myLayer.setItemVisibilityChecked(False)
```

**Is group selected**
```
def isMyGroupSelected( groupName ):
    myGroup = QgsProject.instance().layerTreeRoot().findGroup( groupName )
    return myGroup in iface.layerTreeView().selectedNodes()

print(isMyGroupSelected( 'my group name' ))
```

**Expand node**
```
print(myGroup.isExpanded())
myGroup.setExpanded(False)
```
Hidden node trick

```python
from qgis.core import QgsProject
model = iface.layerTreeView().layerTreeModel()
ltv = iface.layerTreeView()
root = QgsProject.instance().layerTreeRoot()
layer = QgsProject.instance().mapLayersByName('layer name you like')[0]
node = root.findLayer( layer.id() )
index = model.node2index( node )
ltv.setRowHidden( index.row(), index.parent(), True )
node.setCustomProperty( 'nodeHidden', 'true' )
ltv.setCurrentIndex(model.node2index(root))
```

Node signals

```python
def onWillAddChildren(node, indexFrom, indexTo):
    print( "WILL ADD", node, indexFrom, indexTo )

def onAddedChildren(node, indexFrom, indexTo):
    print( "ADDED", node, indexFrom, indexTo )
root.willAddChildren.connect(onWillAddChildren)
root.addedChildren.connect(onAddedChildren)
```

Remove layer

```python
root.removeLayer(layer)
```

Remove group

```python
root.removeChildNode(node_group2)
```

Create new table of contents (TOC)

```python
root = QgsProject.instance().layerTreeRoot()
model = QgsLayerTreeModel(root)
view = QgsLayerTreeView()
view.setModel(model)
view.show()
```

Move node

```python
cloned_group1 = node_group.clone()
root.insertChildNode(0, cloned_group1)
root.removeChildNode(node_group)
```

Rename node

```python
cloned_group1.setName("Group X")
node_layer1.setName("Layer X")
```
20.9 Processing algorithms

Get algorithms list

```python
from qgis.core import QgsApplication
for alg in QgsApplication.processingRegistry().algorithms():
    if 'buffer' == alg.name():
        print(f"{alg.provider().name()} == {alg.name()} --> {alg.displayName()}")
```

QGIS (native c++): buffer --> Buffer

Get algorithms help

Random selection

```python
from qgis import processing
processing.algorithmHelp("native:buffer")
```

... 

Run the algorithm

For this example, the result is stored in a temporary memory layer which is added to the project.

```python
from qgis import processing
result = processing.run("native:buffer", {'INPUT': layer, 'OUTPUT': 'memory:'})
QgsProject.instance().addMapLayer(result['OUTPUT'])
```

Processing(0): Results: {'OUTPUT': 'output_d27a2008_970c_4687_b025_f057abbd7319'}

How many algorithms are there?

```python
len(QgsApplication.processingRegistry().algorithms())
```

How many providers are there?

```python
from qgis.core import QgsApplication
len(QgsApplication.processingRegistry().providers())
```

How many expressions are there?

```python
from qgis.core import QgsExpression
len(QgsExpression.Functions())
```

20.10 Decorators

CopyRight

```python
from qgis.Qt import QTextDocument
from qgis.Qt import QFont
mFont = "Sans Serif"
mFontSize = 9
mLabelQString = "© QGIS 2019"
```

(continues on next page)
mMarginHorizontal = 0
mMarginVertical = 0
mLabelQColor = "#FF0000"

INCHES_TO_MM = 0.0393700787402 # 1 millimeter = 0.0393700787402 inches
case = 2

def add_copyright(p, text, xOffset, yOffset):
    p.translate(xOffset, yOffset)
    text.drawContents(p)
    p.setWorldTransform(p.worldTransform())

        # Top Center
        xOffset = deviceWidth / 2
        add_copyright(p, text, xOffset, yOffset)
    else:
# Bottom Center

```python
yOffset = deviceHeight - yOffset - size.height()
xOffset = deviceWidth / 2
```

```python
# Emitted when the canvas has rendered
iface.mapCanvas().renderComplete.connect(on_render_complete)
```

```python
# Repaint the canvas map
iface.mapCanvas().refresh()
```

## 20.11 Composer

Get print layout by name

```python
composerTitle = 'MyComposer'  # Name of the composer
project = QgsProject.instance()
projectLayoutManager = project.layoutManager()
layout = projectLayoutManager.layoutByName(composerTitle)
```
